

## CC1150

## Low Power Sub-1 GHz RF Transmitter

## Applications

- Ultra low power UHF wireless transmitters
- Operating in the 315/433/868/915 MHz ISM/SRD bands
- AMR – Automatic Meter Reading
- Consumer Electronics
- RKE – Remote Keyless Entry
- Low power telemetry
- Home and building automation
- Wireless alarm and security systems
- Industrial monitoring and control
- Wireless sensor networks

## Product Description

The CC1150 is a low cost true single chip UHF transmitter designed for very low power wireless applications. The circuit is mainly intended for the ISM (Industrial, Scientific and Medical) and SRD (Short Range Device) frequency bands at 315, 433, 868 and 915 MHz, but can easily be programmed for operation at other frequencies in the 300-348 MHz, 400-464 MHz and 800-928 MHz bands.

The RF transmitter is integrated with a highly configurable baseband modulator. The modulator supports various modulation formats and has a configurable data rate up to 500 kBaud. The CC1150 provides extensive hardware support for packet handling, data buffering and burst transmissions.

The main operating parameters and the 64-byte transmit FIFO of CC1150 can be controlled via an SPI interface. In a typical system, the CC1150 will be used together with a micro-controller and a few additional passive components.

CC1150 is part of Chipcon's SmartRF®04 technology platform based on 0.18  $\mu$ m CMOS technology.

## Key Features

- Small size (QLP 4x4 mm package, 16 pins)
- True single chip UHF RF transmitter
- Frequency bands: 300-348 MHz, 400-464 MHz and 800-928 MHz
- Programmable data rate up to 500 kBaud
- Low current consumption
- Programmable output power up to +10 dBm for all supported frequencies
- Programmable baseband modulator
- Ideal for multi-channel operation
- Very few external components: Completely on-chip frequency synthesizer, no external filters needed
- Configurable packet handling hardware
- Suitable for frequency hopping systems due to a fast settling frequency synthesizer
- Optional Forward Error Correction with interleaving
- 64-byte TX data FIFO

## Features (continued from front page)

- Suited for systems compliant with EN 300 220 and FCC CFR Part 15
- Many powerful digital features allow a high-performance RF system to be made using an inexpensive microcontroller
- Efficient SPI interface: All registers can be programmed with one “burst” transfer
- Integrated analog temperature sensor
- Lead-free “green” package
- Flexible support for packet oriented systems: On chip support for sync word insertion, flexible packet length and automatic CRC handling
- OOK and flexible ASK shaping supported
- 2-FSK, GFSK and MSK supported
- Optional automatic whitening of data
- Support for asynchronous transparent transmit mode for backwards compatibility with existing radio communication protocols

## Abbreviations

Abbreviations used in this data sheet are described below.

|      |                                        |       |                                    |
|------|----------------------------------------|-------|------------------------------------|
| ADC  | Analog to Digital Converter            | NRZ   | Non Return to Zero (Coding)        |
| AFC  | Automatic Frequency Compensation       | OOK   | On-Off-Keying                      |
| AGC  | Automatic Gain Control                 | PA    | Power Amplifier                    |
| AMR  | Automatic Meter Reading                | PCB   | Printed Circuit Board              |
| ASK  | Amplitude Shift Keying                 | PD    | Power Down                         |
| BER  | Bit Error Rate                         | PER   | Packet Error Rate                  |
| CCA  | Clear Channel Assessment               | PLL   | Phase Locked Loop                  |
| CFR  | Code of Federal Regulations            | POR   | Power-On Reset                     |
| CRC  | Cyclic Redundancy Check                | QLP   | Quad Leadless Package              |
| CW   | Continuous Wave (Unmodulated Carrier)  | QPSK  | Quadrature Phase Shift Keying      |
| DC   | Direct Current                         | RC    | Resistor-Capacitor                 |
| EIRP | Equivalent Isotropic Radiated Power    | RCOSC | RC Oscillator                      |
| ESR  | Equivalent Series Resistance           | RF    | Radio Frequency                    |
| FCC  | Federal Communications Commission      | RSSI  | Received Signal Strength Indicator |
| FEC  | Forward Error Correction               | RX    | Receive, Receive Mode              |
| FIFO | First-In-First-Out                     | SAW   | Surface Acoustic Wave              |
| FSK  | Frequency Shift Keying                 | SMD   | Surface Mount Device               |
| GFSK | Gaussian shaped Frequency Shift Keying | SNR   | Signal to Noise Ratio              |
| ISM  | Industrial, Scientific, Medical        | SPI   | Serial Peripheral Interface        |
| LC   | Inductor-Capacitor                     | SRD   | Short Range Devices                |
| LO   | Local Oscillator                       | TBD   | To Be Defined                      |
| LSB  | Least Significant Byte                 | TX    | Transmit, Transmit Mode            |
| LQI  | Link Quality Indicator                 | UHF   | Ultra High frequency               |
| MCU  | Microcontroller Unit                   | VCO   | Voltage Controlled Oscillator      |
| MSK  | Minimum Shift Keying                   | XOSC  | Crystal Oscillator                 |
| N/A  | Not Applicable                         | XTAL  | Crystal                            |

## 1 Absolute Maximum Ratings

Under no circumstances must the absolute maximum ratings given in Table 1 be violated. Stress exceeding one or more of the limiting values may cause permanent damage to the device.

**Caution!** ESD sensitive device.  
Precaution should be used when handling the device in order to prevent permanent damage.

| Parameter                                 | Min  | Max                | Units | Condition                                                |
|-------------------------------------------|------|--------------------|-------|----------------------------------------------------------|
| Supply voltage                            | −0.3 | 3.6                | V     | All supply pins must have the same voltage               |
| Voltage on any digital pin                | −0.3 | VDD+0.3<br>max 3.6 | V     |                                                          |
| Voltage on the pins RF_P, RF_N and DCOUPL | −0.3 | 2.0                | V     |                                                          |
| Voltage ramp-up                           |      | 120                | kV/μs |                                                          |
| Input RF level                            |      | +10                | dBm   |                                                          |
| Storage temperature range                 | −50  | 150                | °C    |                                                          |
| Solder reflow temperature                 |      | 260                | °C    | According to IPC/JEDEC J-STD-020C                        |
| ESD                                       |      | <500               | V     | According to JEDEC STD 22, method A114, Human Body Model |

## 2 Operating Conditions

The operating conditions for CC1150 are listed Table 2 in below.

| Parameter                | Min | Max | Unit | Condition                                  |
|--------------------------|-----|-----|------|--------------------------------------------|
| Operating temperature    | −40 | 85  | °C   |                                            |
| Operating supply voltage | 1.8 | 3.6 | V    | All supply pins must have the same voltage |

Table 2: Operating Conditions

## 3 General Characteristics

| Parameter       | Min | Typ | Max | Unit  | Condition/Note                                                                                                                           |
|-----------------|-----|-----|-----|-------|------------------------------------------------------------------------------------------------------------------------------------------|
| Frequency range | 300 |     | 348 | MHz   |                                                                                                                                          |

| Tolerance         |     | ±40 |     | ppm  | This is the total tolerance including a) initial tolerance, b) aging and c) temperature dependence.<br><br>The acceptable crystal tolerance depends on RF frequency and channel spacing / bandwidth |
| Load capacitance  | 10  | 13  | 20  | pF   | Simulated over operating conditions                                                                                                                                                                 |
| ESR               |     |     | 100 | Ω    |                                                                                                                                                                                                     |
| Start-up time     |     | 150 |     | μs   | Measured on the CC1150EM reference design ([1] and [2]). This parameter is to a large degree crystal dependent.                                                                                     |

**Table 6: Crystal Oscillator Parameters**

### 4.4 Frequency Synthesizer Characteristics

T<sub>c</sub> = 25°C, VDD = 3.0 V if nothing else is stated. All measurement results obtained using the CC1150EM reference design ([1] and [2]).

| Parameter                       | Min  | Typ               | Max  | Unit              | Condition/Note                                                                                                                                             |
|---------------------------------|------|-------------------|------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Programmed frequency resolution | 397  | $F_{XOSC}/2^{16}$ | 412  | Hz                | 26 MHz-27 MHz crystals. The resolution (in Hz) is equal for all frequency bands.                                                                           |
| Synthesizer frequency tolerance |      | ±40               |      | ppm               | Given by crystal used. Required accuracy (including temperature and aging) depends on frequency band and channel bandwidth / spacing.                      |
| RF carrier phase noise          |      | -82               |      | dBc/Hz            | @ 50 kHz offset from carrier, carrier at 868 MHz                                                                                                           |
| RF carrier phase noise          |      | -86               |      | dBc/Hz            | @ 100 kHz offset from carrier, carrier at 868 MHz                                                                                                          |
| RF carrier phase noise          |      | -90               |      | dBc/Hz            | @ 200 kHz offset from carrier, carrier at 868 MHz                                                                                                          |
| RF carrier phase noise          |      | -98               |      | dBc/Hz            | @ 500 kHz offset from carrier, carrier at 868 MHz                                                                                                          |
| RF carrier phase noise          |      | -106              |      | dBc/Hz            | @ 1 MHz offset from carrier, carrier at 868 MHz                                                                                                            |
| RF carrier phase noise          |      | -113              |      | dBc/Hz            | @ 2 MHz offset from carrier, carrier at 868 MHz                                                                                                            |
| RF carrier phase noise          |      | -119              |      | dBc/Hz            | @ 5 MHz offset from carrier, carrier at 868 MHz                                                                                                            |
| RF carrier phase noise          |      | -127              |      | dBc/Hz            | @ 10 MHz offset from carrier, carrier at 868 MHz                                                                                                           |
| PLL turn-on / hop time          | 85.1 | 88.4              | 88.4 | μs                | Time from leaving the IDLE state until arriving in the FSTXON or TX state, when not performing calibration. Crystal oscillator running.                    |
| PLL calibration time            | 694  | 18739<br>721      | 721  | XOSC cycles<br>μs | Calibration can be initiated manually or automatically before entering or after leaving TX.<br><br>Min/typ/max time is for 27/26/26 MHz crystal frequency. |

**Table 7: Frequency Synthesizer Parameters**

#### 4.5 Analog Temperature Sensor

T<sub>c</sub> = 25°C, VDD = 3.0 V if nothing else is stated. Note that it is necessary to write 0xBF to the PTEST register to use the analog temperature sensor in the IDLE state.

| Parameter                                 | Min  | Typ   | Max | Unit  | Condition/Note                                                                                                                                                                                                           |
|-------------------------------------------|------|-------|-----|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output voltage at –40°C                   |      | 0.651 |     | V     |                                                                                                                                                                                                                          |
| Output voltage at 0°C                     |      | 0.747 |     | V     |                                                                                                                                                                                                                          |
| Output voltage at +40°C                   |      | 0.847 |     | V     |                                                                                                                                                                                                                          |
| Output voltage at +80°C                   |      | 0.945 |     | V     |                                                                                                                                                                                                                          |
| Temperature coefficient                   |      | 2.45  |     | mV/°C | Fitted from –20°C to +80°C                                                                                                                                                                                               |
| Absolute error in calculated temperature  | –2 * |       | 2 * | °C    | From –20°C to +80°C when using 2.45 mV / °C, after 1-point calibration at room temperature<br>* Indicated minimum and maximum error with 1-point calibration is based on simulated values for typical process parameters |
| Current consumption increase when enabled |      | 0.3   |     | mA    |                                                                                                                                                                                                                          |

**Table 8: Analog Temperature Sensor Parameters**

#### 4.6 DC Characteristics

T<sub>c</sub> = 25°C if nothing else is stated.

| Digital Inputs/Outputs   | Min     | Max | Unit | Condition                     |
|--------------------------|---------|-----|------|-------------------------------|
| Logic "0" input voltage  | 0       | 0.7 | V    |                               |
| Logic "1" input voltage  | VDD-0.7 | VDD | V    |                               |
| Logic "0" output voltage | 0       | 0.5 | V    | For up to 4 mA output current |
| Logic "1" output voltage | VDD-0.3 | VDD | V    | For up to 4 mA output current |
| Logic "0" input current  | N/A     | –1  | μA   | Input equals 0 V              |
| Logic "1" input current  | N/A     | 1   | μA   | Input equals VDD              |

**Table 9: DC Characteristics**

#### 4.7 Power on Reset

For proper Power-On-Reset functionality, the power supply must comply with the requirements in Table 10 below. Otherwise, the chip should be assumed to have unknown state until transmitting an SRES strobe over the SPI interface. See section 16.1 on page 31 for a description of the recommended start up sequence after turning power on.

| Parameter             | Min | Typ | Max | Unit | Condition/Note                              |
|-----------------------|-----|-----|-----|------|---------------------------------------------|
| Power-up ramp-up time |     |     | 5   | ms   | From 0 V until reaching 1.8 V               |
| Power off time        | 1   |     |     | ms   | Minimum time between power-on and power-off |

**Table 10: Power-on Reset Requirements**

## 5 Pin Configuration

The CC1150 pin-out is shown in Figure 1 and Table 11.

**Figure 1: Pinout Top View**

Note: The exposed die attach pad **must** be connected to a solid ground plane as this is the main ground connection for the chip.

| Pin # | Pin name        | Pin type        | Description                                                                                                                                                                                                                                                                        |
|-------|-----------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1     | SCLK            | Digital Input   | Serial configuration interface, clock input.                                                                                                                                                                                                                                       |
| 2     | SO (GD01)       | Digital Output  | Serial configuration interface, data output.<br>Optional general output pin when CSn is high.                                                                                                                                                                                      |
| 3     | DVDD            | Power (Digital) | 1.8 V - 3.6 V digital power supply for digital I/O's and for the digital core voltage regulator.                                                                                                                                                                                   |
| 4     | DCOUP           | Power (Digital) | 1.6 V - 2.0 V digital power supply output for decoupling.<br>NOTE: This pin is intended for use with the CC1150 only. It can not be used to provide supply voltage to other devices.                                                                                               |
| 5     | XOSC_Q1         | Analog I/O      | Crystal oscillator pin 1, or external clock input.                                                                                                                                                                                                                                 |
| 6     | AVDD            | Power (Analog)  | 1.8 V - 3.6 V analog power supply connection.                                                                                                                                                                                                                                      |
| 7     | XOSC_Q2         | Analog I/O      | Crystal oscillator pin 2.                                                                                                                                                                                                                                                          |

**Table 11: Pinout Overview**

## 6 Circuit Description

Figure 2: CC1150 Simplified Block Diagram

A simplified block diagram of CC1150 is shown in Figure 2.

The CC1150 transmitter is based on direct synthesis of the RF frequency. The frequency synthesizer includes a completely on-chip LC VCO.

A crystal is to be connected to XOSC\_Q1 and XOSC\_Q2. The crystal oscillator generates the reference frequency for the synthesizer, as

well as clocks for the digital part.

A 4-wire SPI serial interface is used for configuration and data buffer access.

The digital baseband includes support for channel configuration, packet handling and data buffering.

## 7 Application Circuit

Only a few external components are required for using the CC1150. The recommended application circuits are shown in Figure 4 and

Figure 5. The external components are described in Table 13, and typical values are given in Table 14.

### 7.1 Bias resistor

The bias resistor R141 is used to set an

accurate bias current.

### 7.2 Balun and RF matching

The components between the RF\_N/RF\_P pins and the point where the two signals are joined together (C111, C101, L101 and L111 for the 315/433 MHz design. L101, L111, C101, L102, C111, C102 and L112 for the 868/915 MHz reference design) form a balun that converts the differential RF signal on CC1150 to a single-ended RF signal. C104 is needed for DC blocking. Together with an appropriate LC filter network, the balun components also transform the impedance to match a 50  $\Omega$  antenna (or cable). C105 provides DC blocking and is only needed if there is a DC path in the antenna. For the

868/915 MHz reference design, this component may also be used for additional filtering, see section 7.5 below.

Suggested values for 315 MHz, 433 MHz and 868/915 MHz are listed in Table 14.

The balun and LC filter component values and their placement are important to achieve optimal performance. It is highly recommended to follow the CC1150EM reference design ([1] and [2]). Gerber files and schematics for the reference designs are available for download from the TI website.

### 7.3 Crystal

A crystal in the frequency range 26-27 MHz must be connected between the XOSC\_Q1 and XOSC\_Q2 pins. The oscillator is designed for parallel mode operation of the crystal. In addition, loading capacitors (C51 and C71) for the crystal are required. The loading capacitor values depend on the total load capacitance,  $C_L$ , specified for the crystal. The total load capacitance seen between the crystal terminals should equal  $C_L$  for the crystal to oscillate at the specified frequency.

$$C_L = \frac{1}{\frac{1}{C_{51}} + \frac{1}{C_{71}}} + C_{\text{parasitic}}$$

The parasitic capacitance is constituted by pin input capacitance and PCB stray capacitance. Total parasitic capacitance is typically 2.5 pF.

The crystal oscillator circuit is shown in Figure 3. Typical component values for different values of  $C_L$  are given in Table 12.

**Figure 3: Crystal Oscillator Circuit**

The crystal oscillator is amplitude regulated. This means that a high current is used to start up the oscillations. When the amplitude builds up, the current is reduced to what is necessary to maintain approximately 0.4 V<sub>pp</sub> signal swing. This ensures a fast start-up, and keeps the drive level to a minimum. The ESR of the crystal should be within the specification in order to ensure a reliable start-up (see section 4.3 on page 8).

The initial tolerance, temperature drift, aging and load pulling should be carefully specified in order to meet the required frequency accuracy in a certain application.

| Component | $C_L = 10 \text{ pF}$ | $C_L = 13 \text{ pF}$ | $C_L = 16 \text{ pF}$ |
|-----------|-----------------------|-----------------------|-----------------------|
| C51       | 15 pF                 | 22 pF                 | 27 pF                 |
| C71       | 15 pF                 | 22 pF                 | 27 pF                 |

**Table 12: Crystal Oscillator Component Values**

### 7.4 Reference signal

The chip can alternatively be operated with a reference signal from 26 to 27 MHz instead of a crystal. This input clock can either be a full-swing digital signal (0 V to VDD) or a sine wave of maximum 1 V peak-peak amplitude. The reference signal must be connected to the

XOSC\_Q1 input. The sine wave must be connected to XOSC\_Q1 using a serial capacitor. The XOSC\_Q2 line must be left unconnected. C51 and C71 can be omitted when using a reference signal.

### 7.5 Additional filtering

In the 868/915 MHz reference design, C106 and L105 together with C105 build an optional filter to reduce emission at 699 MHz. This filter may be necessary for applications seeking compliance with ETSI EN 300-220, for more information, see DN017 [6]. If this filtering is not necessary, C105 will work as a DC block (only necessary if there is a DC path in the antenna). C106 and L105 should in that case be left unmounted.

Additional external components (e.g. an RF SAW filter) may be used in order to improve the performance in specific applications. The use of wire-wound inductors in the application circuit will also improve the RF performance and give higher output power. For more information, see DN017 [6].

### 7.6 Power supply decoupling

The power supply must be properly decoupled close to the supply pins. Note that decoupling capacitors are not shown in the application circuit. The placement and the size of the

decoupling capacitors are very important to achieve the optimum performance. The CC1150EM reference design should be followed closely ([1] and [2]).

## 7.7 Antenna Considerations

The reference designs ([1] and [2]) contains a SMA connector and is match for a 50  $\Omega$  load. The SMA connector makes it easy to connect evaluation modules and prototypes to different test equipment for example a spectrum analyzer. The SMA connector can also be

replaced by an antenna suitable for the desired application. Please refer to the antenna selection guide AN058 [7] for further details regarding antenna solutions provided by TI.

| Component | Description                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------|
| C41       | Decoupling capacitor for on-chip voltage regulator to digital part                                                               |

## 7.8 PCB Layout Recommendations

The top layer should be used for signal routing, and the open areas should be filled with metallization connected to ground using several vias.

The area under the chip is used for grounding and shall be connected to the bottom ground plane with several vias for good thermal performance and sufficiently low inductance to ground.

In the CC1150EM reference designs ([1] and [2]), 5 vias are placed inside the exposed die attached pad. These vias should be “tented” (covered with solder mask) on the component side of the PCB to avoid migration of solder through the vias during the solder reflow process.

The solder paste coverage should not be 100%. If it is, out gassing may occur during the reflow process, which may cause defects (splattering, solder balling). Using “tented” vias

reduces the solder paste coverage below 100%. See Figure 6 for top solder resist and top paste masks.

All the decoupling capacitors should be placed as close as possible to the supply pin it is supposed to decouple. Each decoupling capacitor should be connected to the power line (or power plane) by separate vias. The best routing is from the power line (or power plane) to the decoupling capacitor and then to the CC1150 supply pin. Supply power filtering is very important.

Each decoupling capacitor ground pad should be connected to the ground plane by separate vias. Direct connections between neighboring power pins will increase noise coupling and should be avoided unless absolutely necessary. Routing in the ground plane underneath and between the chip, the balun/RF matching circuit and the decoupling capacitor's ground vias should also be

avoided. This improves the grounding and ensures the shortest possible return path for stray currents.

The external components should ideally be as small as possible (0402 is recommended) and surface mount devices are highly recommended. Please note that components smaller than those specified may have differing characteristics.

Precaution should be used when placing the microcontroller in order to avoid noise interfering with the RF circuitry.

It is strongly advised that the CC1150EM reference design ([1] and [2]) layout is followed very closely in order to get the best performance. Gerber files and schematics for the reference designs are available for download from the TI website.

## 8 Configuration Overview

CC1150 can be configured to achieve optimum performance for many different applications. Configuration is done using the SPI interface. The following key parameters can be programmed:

- Power-down / power-up mode
- Crystal oscillator power-up / power – down
- Transmit mode
- RF channel selection
- Data rate
- Modulation format
- RF output power
- Data buffering with 64-byte transmit FIFO
- Packet radio hardware support

- Forward Error Correction with interleaving
- Data Whitening

Details of each configuration register can be found in section 25, starting on page 42.

Figure 7 shows a simplified state diagram that explains the main CC1150 states, together with typical usage and current consumption. For detailed information on controlling the CC1150 state machine, and a complete state diagram, see section 16, starting on page 30.

Figure 7: Simplified State Diagram with Typical Usage and Current Consumption

## 9 Configuration Software

CC1150 can be configured using the SmartRF® Studio [11] software, available for download from [www.ti.com/smartrfstudio](http://www.ti.com/smartrfstudio). The SmartRF Studio software is highly recommended for obtaining optimum register settings, and for evaluating performance and functionality. A screenshot of the SmartRF Studio user interface for CC1150 is shown in Figure 8.

After chip reset, all the registers have default values as shown in the tables in section 25. The optimum register setting might differ from the default value. After a reset all registers that shall be different from the default value therefore needs to be programmed through the SPI interface.

Figure 8: SmartRF Studio User Interface

## 10 4-wire Serial Configuration and Data Interface

CC1150 is configured via a simple 4-wire SPI-compatible interface (SI, SO, SCLK and CSn) where CC1150 is the slave. This interface is also used to read and write buffered data. All address and data transfer on the SPI interface is done most significant bit first.

All transactions on the SPI interface start with a header byte containing a read/write bit, a burst access bit and a 6-bit address.

During address and data transfer, the CSn pin (Chip Select, active low) must be kept low. If CSn goes high during the access, the transfer will be cancelled. The timing for the address

and data transfer on the SPI interface is shown in Figure 9 with reference to Table 15.

When CSn is pulled low, the MCU must wait until the CC1150SO pin goes low before starting to transfer the header byte. This indicates that the voltage regulator has stabilized and the crystal is running. Unless the chip is in the SLEEP or XOFF states, the SO pin will always go low immediately after taking CSn low.

Figure 9: Configuration Registers Write and Read Operations

| Parameter           | Description                                                                                                                                                         | Min           | Max | Units         |

| $t_{\text{cl}}$     | Clock low                                                                                                                                                           | 50            | -   | ns            |
| $t_{\text{rise}}$   | Clock rise time                                                                                                                                                     | -             | 5   | ns            |
| $t_{\text{fall}}$   | Clock fall time                                                                                                                                                     | -             | 5   | ns            |
| $t_{\text{sd}}$     | Setup data (negative SCLK edge) to positive edge on SCLK<br>( $t_{\text{sd}}$ applies between address and data bytes, and between data bytes)                       | Single access | 55  | - ns          |
|                     |                                                                                                                                                                     | Burst access  | 76  | - ns          |
| $t_{\text{hd}}$     | Hold data after positive edge on SCLK                                                                                                                               | 20            | -   | ns            |
| $t_{\text{ns}}$     | Negative edge on SCLK to CSn high                                                                                                                                   | 20            | -   | ns            |

Table 15: SPI Interface Timing Requirements

Note that the minimum  $t_{\text{sp, pd}}$  figure in Table 15 can be used in cases where the user does not read the CHIP\_RDYn signal. CSn low to positive edge on SCLK when the chip is woken from power-down depends on the start-up time of the crystal being used. The 150  $\mu\text{s}$  in Table 15 is the crystal oscillator start-up time measured using crystal AT-41CD2 from NDK.

### 10.1 Chip Status Byte

When the header byte, data byte or command strobe is sent on the SPI interface, the chip status byte is sent by the CC1150 on the S0 pin. The status byte contains key status signals, useful for the MCU. The first bit, s7, is the CHIP\_RDYn signal; this signal must go low before the first positive edge of SCLK. The CHIP\_RDYn signal indicates that the crystal is running and the regulated digital supply voltage is stable.

Bit 6, 5 and 4 comprises the STATE value. This value reflects the state of the chip. The XOSC and power to the digital core is on in the IDLE state, but all other modules are in power down. The frequency and channel configuration should only be updated when the chip is in this state. The TX state will be active when the chip is transmitting.

The last four bits (3:0) in the status byte contains FIFO\_BYTES\_AVAILABLE. This field

contains the number of bytes free for writing into the TX FIFO. When FIFO\_BYTES\_AVAILABLE=15, 15 or more

bytes are free. Table 16 gives a status byte summary.

| Bits  | Name                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |       |       |             |     |      |                                                                                                                   |     |          |          |     |    |               |     |        |               |     |           |                                              |     |          |                 |     |          |          |     |                  |                                                |
|-------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------|-------------|-----|------|-------------------------------------------------------------------------------------------------------------------|-----|----------|----------|-----|----|---------------|-----|--------|---------------|-----|-----------|----------------------------------------------|-----|----------|-----------------|-----|----------|----------|-----|------------------|------------------------------------------------|
| 7     | CHIP_RDYn                 | Stays high until power and crystal have stabilized. Should always be low when using the SPI interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |       |             |     |      |                                                                                                                   |     |          |          |     |    |               |     |        |               |     |           |                                              |     |          |                 |     |          |          |     |                  |                                                |

**Table 16: Status Byte Summary**

## 10.2 Register Access

The configuration registers on the *CC1150* are located on SPI addresses from 0x00 to 0x2E. Table 26 on page 43 lists all configuration registers. The detailed description of each register is found in Section 25.1, starting on page 45.

All configuration registers can be both written and read. The read/write bit controls if the register should be written or read. When writing to registers, the status byte is sent on the SO pin each time a header byte or data byte is transmitted on the SI pin. When reading from registers, the status byte is sent on the SO pin each time a header byte is transmitted on the SI pin.

Registers with consecutive addresses can be accessed in an efficient way by setting the burst bit in the address header. The address sets the start address in an internal address counter. This counter is incremented by one each new byte (every 8 clock pulses). The burst access is either a read or a write access and must be terminated by setting CSn high.

For register addresses in the range 0x30-0x3D, the burst bit is used to select between status registers (burst bit is 1) and command strobes (burst bit is 0). See more in section 10.3 below. Because of this, burst access is not available for status registers, so they must be read one at a time. The status registers can only be read.

## 10.3 SPI Read

When reading register fields over the SPI interface while the register fields are updated by the radio hardware (e.g. MARCSTATE or TXBYTES), there is a small, but finite, probability that a single read from the register

is being corrupt. As an example, the probability of any single read from TXBYTES being corrupt, assuming the maximum data rate is used, is approximately 80 ppm. Refer to the *CC1150* Errata Notes [8] for more details.

## 10.4 Command Strokes

Command Strokes may be viewed as single byte instructions to *CC1150*. By addressing a Command Strobe register, internal sequences

will be started. These commands are used to disable the crystal oscillator, enable transmit mode, flush the TX FIFO etc. The nine

command strobes are listed in Table 25 on page 42.

Note that an SIDLE strobe will clear all pending command strobes until IDLE state is reached. This means that if for example an SIDLE strobe is issued while the radio is in TX state, any other command strobes issued before the radio reaches IDLE state will be ignored.

The command strobe registers are accessed in the same way as for a register write operation, but no data is transferred. That is, only the R/W bit (set to 0), burst access (set to 0) and the six address bits (in the range 0x30 through 0x3D) are written.

When writing command strobes, the status byte is sent on the S0 pin.

A command strobe may be followed by any other SPI access without pulling CSn high.

However, if an SRES command strobe is being issued, one will have to wait for the S0 pin to go low before the next command strobe can be issued as shown in Figure 10. The command strobes are executed immediately, with the exception of the SPWD and the SXOFF strobes that are executed when CSn goes high.

Figure 10: SRES Command Strobe

## 10.5 FIFO Access

The 64-byte TX FIFO is accessed through the 0x3F addresses. When the read/write bit is zero, the TX FIFO is accessed. The TX FIFO is write-only.

The burst bit is used to determine if FIFO access is single byte or a burst access. The single byte access method expects address with burst bit set to zero and one data byte. After the data byte a new address is expected; hence, CSn can remain low. The burst access method expects one address byte and then consecutive data bytes until terminating the access by setting CSn high.

The following header bytes access the FIFO:

- 0x3F: Single byte access to TX FIFO
- 0x7F: Burst access to TX FIFO

When writing to the TX FIFO, the status byte (see Section 10.1) is output for each new data byte on S0, as shown in Figure 10. This status byte can be used to detect TX FIFO underflow

while writing data to the TX FIFO. Note that the status byte contains the number of bytes free *before* writing the byte in progress to the TX FIFO. When the last byte that fits in the TX FIFO is transmitted to the SI pin, the status byte received concurrently on the SO pin will indicate that one byte is free in the TX FIFO.

The TX FIFO may be flushed by issuing a SFTX command strobe. The SFTX command strobe can only be issued in the IDLE or TX\_UNDERFLOW states. The FIFO is cleared when going to the SLEEP state.

Figure 11 gives a brief overview of different register access types possible.

Figure 11: Register Access Types

## 10.6 PATABLE Access

The 0x3E address is used to access the PATABLE, which is used for selecting PA power control settings. The SPI expects up to eight data bytes after receiving the address. By programming the PATABLE, controlled PA power ramp-up and ramp-down can be achieved, as well as ASK modulation shaping for reduced bandwidth. Note that the ASK modulation shaping is limited to output powers below -1 dBm. See SmartRF Studio [11] for recommended shaping sequence. See also section 21 on page 35 for details on output power programming.

The PATABLE is an 8-byte table that defines the PA control settings to use for each of the eight PA power values (selected by the 3-bit value `FREND0.PA_POWER`). The table is written and read from the lowest setting (0) to the highest (7), one byte at a time. An index counter is used to control the access to the

table. This counter is incremented each time a byte is read or written to the table, and set to the lowest index when CSn is high. When the highest value is reached the counter restarts at zero.

The access to the PATABLE is either single byte or burst access depending on the burst bit. When using burst access the index counter will count up; when reaching 7 the counter will restart at 0. The read/write bit controls whether the access is a write access (R/W=0) or a read access (R/W=1).

If one byte is written to the PATABLE and this value is to be read out then CSn must be set high before the read access in order to set the index counter back to zero.

Note that the content of the PATABLE is lost when entering the SLEEP state. For more information, see DN501 [8].

## 11 Microcontroller Interface and Pin Configuration

In a typical system, CC1150 will interface to a microcontroller. This microcontroller must be able to:

- Program CC1150 into different modes,

- Write buffered data
- Read back status information via the 4-wire SPI-bus configuration interface (SI, SO, SCLK and CSn).

### 11.1 Configuration Interface

The microcontroller uses four I/O pins for the SPI configuration interface (SI, SO, SCLK and

CSn). The SPI is described in Section 10 on page 18.

### 11.2 General Control and Status Pins

The CC1150 has one dedicated configurable pin (GD00) and one shared pin (GD01/S0) that can output internal status information useful for control software. These pins can be used to generate interrupts on the MCU. See section 22 page 37 for more details of the signals that can be programmed. The shared pin is the S0 pin in the SPI interface. The default setting for GD01/S0 is 3-state output. By selecting any other of the programming options the GD01/S0 pin will become a generic pin. When CSn is low, the pin will always function as a normal S0 pin.

In the synchronous and asynchronous serial modes, the GD00 pin is used as a serial TX data input pin while in transmit mode.

The GD00 pin can also be used for an on-chip analog temperature sensor. By measuring the voltage on the GD00 pin with an external ADC, the temperature can be calculated. Specifications for the temperature sensor are found in section 4.5 on page 9. With default PTEST register setting (0x7F), the temperature sensor output is only available when the frequency synthesizer is enabled (e.g. the MANCAL, FSTXON and TX states). It is necessary to write 0xBF to the PTEST register to use the analog temperature sensor in the IDLE state. Before leaving the IDLE state, the PTEST register should be restored to its default value (0x7F).

### 11.3 Optional Radio Control Feature

The CC1150 has an optional way of controlling the radio by reusing SI, SCLK, and CSn from the SPI interface. This feature allows for a simple three-pin control of the major states of the radio: SLEEP, IDLE, and TX.

This optional functionality is enabled with the MCSM0.PIN\_CTRL\_EN configuration bit.

State changes are commanded as follows:

- If CSn is high, the SI and SCLK are set to the desired state according to Table 17.
- If CSn goes low, the state of SI and SCLK is latched and a command strobe is generated internally according to the pin configuration.

It is only possible to change state with the latter functionality. That means that for instance TX will not be restarted if SI and

SCLK are set to TX and CSn toggles. When CSn is low the SI and SCLK has normal SPI functionality.

All pin control command strobes are executed immediately except the SPWD strobe. The SPWD strobe is delayed until CSn goes high.

| CSn | SCLK     | SI       | Function                                       |
|-----|----------|----------|------------------------------------------------|
| 1   | X        | X        | Chip unaffected by SCLK/SI                     |
| ↓   | 0        | 0        | Generates SPWD strobe                          |
| ↓   | 0        | 1        | Generates STX strobe                           |
| ↓   | 1        | 0        | Generates SIDLE strobe                         |
| ↓   | 1        | 1        | Defined on the transceiver version (CC1101)    |
| 0   | SPI mode | SPI mode | SPI mode (wakes up into IDLE if in SLEEP/XOFF) |

Table 17: Optional Pin Control Coding

## 12 Data Rate Programming

The data rate used when transmitting is programmed by the MDMCFG3.DRATE\_M and the MDMCFG4.DRATE\_E configuration registers. The data rate is given by the formula below. As the formula shows, the programmed data rate depends on the crystal frequency.

$$R_{DATA} = \frac{(256 + DRATE\_M) \cdot 2^{DRATE\_E}}{2^{28}} \cdot f_{XOSC}$$

The following approach can be used to find suitable values for a given data rate:

$$DRATE\_E = \left\lceil \log_2 \left( \frac{R_{DATA} \cdot 2^{20}}{f_{XOSC}} \right) \right\rceil$$

$$DRATE\_M = \frac{R_{DATA} \cdot 2^{28}}{f_{XOSC} \cdot 2^{DRATE\_E}} - 256$$

If DRATE\_M is rounded to the nearest integer and becomes 256, increment DRATE\_E and use DRATE\_M=0.

The data rate can be set from 0.8 kBaud to 500 kBaud with the minimum data rate step size changes according to Table 18 below.

| Min Data rate [kBaud] | Typical data rate [kBaud] | Max Data rate [kBaud] | Data rate step size [kBaud] |
|-----------------------|---------------------------|-----------------------|-----------------------------|
| 0.8                   | 1.2 / 2.4                 | 3.17                  | 0.0062                      |
| 3.17                  | 4.8                       | 6.35                  | 0.0124                      |
| 6.35                  | 9.6                       | 12.7                  | 0.0248                      |
| 12.7                  | 19.6                      | 25.4                  | 0.0496                      |
| 25.4                  | 38.4                      | 50.8                  | 0.0992                      |
| 50.8                  | 76.8                      | 101.6                 | 0.1984                      |
| 101.6                 | 153.6                     | 203.1                 | 0.3967                      |
| 203.1                 | 250                       | 406.3                 | 0.7935                      |
| 406.3                 | 500                       | 500                   | 1.5869                      |

Table 18: Data Rate Step Size

## 13 Packet Handling Hardware Support

The *CC1150* has built-in hardware support for packet oriented radio protocols.

In transmit mode, the packet handler can be configured to add the following elements to the packet stored in the TX FIFO:

- A programmable number of preamble bytes.
- A two byte Synchronization Word. Can be duplicated to give a 4-byte sync word (recommended). It is not possible to only insert preamble or only insert a sync word.
- Optionally whitening the data with a PN9 sequence.
- Optionally Interleave and Forward Error Code the data.

- Optionally compute and add a 2 byte CRC checksum over the data field.

In a system where *CC1150* is used as the transmitter and *CC1101* as the receiver the recommended setting is 4-byte preamble and 4-byte sync word except for 500 kBaud data rate where the recommended preamble length is 8 bytes.

Note that register fields that control the packet handling features should only be altered when *CC1150* is in the IDLE state.

### 13.1 Data whitening

From a radio perspective, the ideal over the air data are random and DC free. This results in the smoothest power distribution over the occupied bandwidth. This also gives the regulation loops in the receiver uniform operation conditions (no data dependencies).

Real world data often contain long sequences of zeros and ones. Performance can then be improved by whitening the data before transmitting, and de-whitening in the receiver. With *CC1150*, in combination with a *CC1101* at the receiver end, this can be done automatically by setting PKTCTRL0

.WHITE\_DATA=1. All data, except the preamble and the sync word, are then XOR-ed with a 9-bit pseudo-random (PN9) sequence before being transmitted as shown in Figure 12. The PN9 sequence is initialized to all 1's. At the receiver end, the data are XOR-ed with the same pseudo-random sequence. This way, the whitening is reversed, and the original data appear in the receiver.

Setting PKTCTRL0 .WHITE\_DATA=1 is recommended for all uses, except when over-the-air compatibility with other systems is needed.

Figure 12: Data Whitening in TX Mode

### 13.2 Packet Format

The format of the data packet can be configured and consists of the following items:

- Preamble
- Synchronization word
- Optional length byte
- Optional Address byte
- Payload
- Optional 2 byte CRC

Figure 13: Packet Format

The preamble pattern is an alternating sequence of ones and zeros (01010101...). The number of preamble bytes is programmed with the `MDMCFG1.NUM_PREAMBLE` value. When enabling TX, the modulator will start transmitting the preamble. When the programmed number of preamble bytes has been transmitted, the modulator will send the sync word and then data from the TX FIFO if data is available. If the TX FIFO is empty, the modulator will continue to send preamble bytes until the first byte is written to the TX FIFO. The modulator will then send the sync word and then the data bytes.

The synchronization word is a two-byte value set in the `SYNC1` and `SYNC0` registers. The sync word provides byte synchronization of the incoming packet. A one-byte synch word can be emulated by setting the `SYNC1` value to the preamble pattern. It is also possible to emulate a 32 bit sync word by using `MDMCFG2.SYNC_MODE` set to 3 or 7. The sync word will then be repeated twice.

CC1150 supports both fixed packet length protocols and variable packet length protocols. Variable or fixed packet length mode can be used for packets up to 255 bytes. For longer packets, infinite packet length mode must be used.

Fixed packet length mode is selected by setting `PKTCTRL0.LENGTH_CONFIG=0`. The desired packet length is set by the `PKTLEN` register. In variable packet length mode `PKTCTRL0.LENGTH_CONFIG=1`, the packet length is configured by the first byte after the sync word. The packet length is defined as the

payload data, excluding the length byte and the optional automatic CRC.

With `PKTCTRL0.LENGTH_CONFIG=2`, the packet length is set to infinite and transmission will continue until turned off manually. The infinite mode can be turned off while a packet is being transmitted. As described in the next section, this can be used to support packet formats with different length configuration than natively supported by CC1150. One should make sure that TX mode is not turned off during the transmission of the first half of any byte. Refer to the CC1150 Errata Notes [8] for more details.

Note that the minimum packet length supported (excluding the optional length byte and CRC) is one byte of payload data.

#### 13.2.1 Arbitrary Length Field Configuration

The packet automation control register, `PKTCTRL0`, can be reprogrammed during TX. This opens the possibility to transmit packets that are longer than 256 bytes and still be able to use the packet handling hardware support. At the start of the packet, the infinite mode (`PKTCTRL0.LENGTH_CONFIG=2`) must be active. The `PKTLEN` register is set to `mod(length, 256)`. When less than 256 bytes remains of the packet, the MCU disables infinite packet length and activates fixed length packets. When the internal byte counter reaches the `PKTLEN` value, the transmission ends (the radio enters the state determined by `TXOFF_MODE`). Automatic CRC appending can be used (by setting `PKTCTRL0.CRC_EN=1`).

When for example a 600-byte packet is to be transmitted, the MCU should do the following (see also Figure 14):

- Set `PKTCTRL0.LENGTH_CONFIG=2`.
- Pre-program the `PKTLEN` register to  $\text{mod}(600, 256)=88$ .
- Transmit at least 345 bytes, for example by filling the 64-byte TX FIFO six times (384 bytes transmitted).
- Set `PKTCTRL0.LENGTH_CONFIG=0`.
- The transmission ends when the packet counter reaches 88. A total of 600 bytes are transmitted.

**Figure 14: Arbitrary Length Field Configuration**

### 13.3 Packet Handling in Transmit Mode

The payload that is to be transmitted must be written into the TX FIFO. The first byte written must be the length byte when variable packet length is enabled. The length byte has a value equal to the payload of the packet (including the optional address byte). If fixed packet length is enabled, then the first byte written to the TX FIFO is interpreted as the destination address, if this feature is enabled in the device that receives the packet.

The modulator will first send the programmed number of preamble bytes. If data is available in the TX FIFO, the modulator will send the two-byte (optionally 4-byte) sync word and then the payload in the TX FIFO. If CRC is enabled, the checksum is calculated over all the data pulled from the TX FIFO and the result is sent as two extra bytes at the end of

the payload data. If the TX FIFO runs empty before the complete packet has been transmitted, the radio will enter `TXFIFO_UNDERFLOW` state. The only way to exit this state is by issuing an `SFTX` strobe. Writing to the TX FIFO after it has underflowed will not restart TX mode.

If whitening is enabled, the length byte, payload data and the two CRC bytes will be whitened. This is done before the optional FEC/Interleaver stage. Whitening is enabled by setting `PKTCTRL0.WHITE_DATA=1`.

If FEC/Interleaving is enabled, the length byte, payload data and the two CRC bytes will be scrambled by the interleaver, and FEC encoded before being modulated. FEC is enabled by setting `MDMCFG1.FEC_EN=1`.

### 13.4 Packet Handling in Firmware

When implementing a packet oriented radio protocol in firmware, the MCU needs to know when a packet has been transmitted. Additionally, for packets longer than 64 bytes, the TX FIFO needs to be refilled while in TX. This means that the MCU needs to know the number of bytes that can be written to the TX FIFO. There are two possible solutions to get the necessary status information:

a) Interrupt Driven Solution

The GDO pins can be used in TX to give an interrupt when a sync word has been transmitted or when a complete packet has been transmitted by setting `IOCFGx.GDOx_CFG=0x06`. In addition, there are two configurations for the `IOCFGx.GDOx_CFG` register that can be used as an interrupt source to provide information on how many bytes that is in the TX FIFO. The `IOCFGx.GDOx_CFG=0x02` and the

IOCFGx.GDOx\_CFG=0x03 configurations are associated with the TX FIFO. See Table 24 for more information.

## b) SPI Polling

The PKTSTATUS register can be polled at a given rate to get information about the current GDO2 and GDO0 values respectively. The TXBYTES register can be polled at a given rate to get information about the number of bytes in the TX FIFO. Alternatively, the number of bytes in the TX FIFO can be read from the chip status byte returned on the MISO line

each time a header byte, data byte, or command strobe is sent on the SPI bus.

It is recommended to employ an interrupt driven solution due to that when using SPI polling, there is a small, but finite, probability that a single read from registers PKTSTATUS and TXBYTES is being corrupt. The same is the case when reading the chip status byte. This is explained in the *CC1150* Errata Notes [8] Refer to the TI website for SW examples [12]

## 14 Modulation Formats

*CC1150* supports amplitude, frequency and phase shift modulation formats. The desired modulation format is set in the MDMCFG2.MOD\_FORMAT register.

Optionally, the data stream can be Manchester coded by the modulator. This option is enabled

by setting MDMCFG2.MANCHESTER\_EN=1. Manchester encoding cuts the effective data rate in half, and thus Manchester is not supported for 500 kBaud. Further note that Manchester encoding is not supported at the same time as using the FEC/Interleaver option or when using MSK modulation.

### 14.1 Frequency Shift Keying

*CC1150* has the possibility to use Gaussian shaped 2\_FSK (GFSK). The 2-FSK signal is then shaped by a Gaussian filter with BT=1, producing a GFSK modulated signal. This spectrum-shaping feature improves adjacent channel power (ACP) and occupied bandwidth.

In “true” 2-FSK systems with abrupt frequency shifting, the spectrum is inherently broad. By making the frequency shift “softer”, the spectrum can be made significantly narrower. Thus, higher data rates can be transmitted in the same bandwidth using GFSK.

The frequency deviation is programmed with the DEVIATION\_M and DEVIATION\_E values in the DEVIATN register. The value has an

exponent/mantissa form, and the resultant deviation is given by:

$$f_{dev} = \frac{f_{xosc}}{2^{17}} \cdot (8 + DEVIATION\_M) \cdot 2^{DEVIATION\_E}$$

The symbol encoding is shown in Table 19.

| Format     | Symbol | Coding      |
|------------|--------|-------------|
| 2-FSK/GFSK | '0'    | – Deviation |
|            | '1'    | + Deviation |

**Table 19: Symbol Encoding for 2-FSK/GFSK Modulation**

### 14.2 Minimum Shift Keying

When using MSK<sup>1</sup>, the complete transmission (preamble, sync word and payload) will be MSK modulated.

Phase shifts are performed with a constant transition time. The fraction of a symbol period

used to change the phase can be modified with the DEVIATN.DEVIATION\_M setting. This is equivalent to changing the shaping of the symbol.

Note that when using MSK, Manchester encoding must be disabled by setting MDMCFG2.MANCHESTER\_EN=0. Further note that the MSK modulation format implemented in *CC1150* inverts the data compared to e.g. signal generators.

<sup>1</sup> Identical to offset QPSK with half-sine shaping (data coding may differ)

### 14.3 Amplitude Modulation

CC1150 supports two different forms of amplitude modulation: On-Off Keying (OOK) and Amplitude Shift Keying (ASK).

OOK modulation simply turns on or off the PA to modulate 1 and 0 respectively.

The ASK variant supported by the CC1150 allows programming of the modulation depth (the difference between 1 and 0), and shaping

of the pulse amplitude. Pulse shaping will produce a more bandwidth constrained output spectrum.

Note that the OOK/ASK pulse shaping feature on the CC1150 does only support output power up to about -1 dBm.

The DEVIATN register has no effect when using ASK/OOK.

## 15 Forward Error Correction with Interleaving

### 15.1 Forward Error Correction (FEC)

CC1150 has built in support for Forward Error Correction (FEC) that can be used with CC1101 at the receiver end. To enable this option, set `MDMCFG1.FEC_EN` to 1. FEC is only supported in fixed packet length mode, i.e. when `PKTCTRL0.LENGTH_CONFIG=0`. FEC is employed on the data field and CRC word in order to reduce the gross bit error rate when operating near the sensitivity limit. Redundancy is added to the transmitted data in such a way that the receiver can restore the original data in the presence of some bit errors.

The use of FEC allows correct reception at a lower Signal-to-Noise RATIO (SNR), thus extending communication range. Alternatively, for a given SNR, using FEC decreases the bit error rate (BER). As the packet error rate (PER) is related to BER by

$$PER = 1 - (1 - BER)^{packet\_length}$$

A lower BER can be used to allow longer packets, or a higher percentage of packets of a given length, to be transmitted successfully.

Finally, in realistic ISM radio environments, transient and time-varying phenomena will produce occasional errors even in otherwise good reception conditions. FEC will mask such errors and, combined with interleaving of the coded data, even correct relatively long periods of faulty reception (burst errors).

The FEC scheme adopted for CC1150 is convolutional coding, in which  $n$  bits are generated based on  $k$  input bits and the  $m$  most recent input bits, forming a code stream able to withstand a certain number of bit errors between each coding state (the  $m$ -bit window).

The convolutional coder is a rate 1/2 code with a constraint length of  $m=4$ . The coder codes one input bit and produces two output bits; hence, the effective data rate is halved. This means that in order to transmit at the same effective data rate when using FEC, it is necessary to use twice as high over-the-air data rate.

### 15.2 Interleaving

Data received through real radio channels will often experience burst errors due to interference and time-varying signal strengths. In order to increase the robustness to errors spanning multiple bits, interleaving is used when FEC is enabled. After de-interleaving, a continuous span of errors in the received stream will become single errors spread apart.

CC1150 employs matrix interleaving, which is illustrated in Figure 15. The on-chip interleaving buffer is a 4 x 4 matrix. In the transmitter, the data bits are written into the

rows of the matrix, whereas the bit sequence to be transmitted is read from the columns of the matrix and fed to the rate 1/2 convolutional coder. Conversely, in a CC1101 receiver, the received symbols are written into the rows of the matrix, whereas the data passed onto the convolutional decoder is read from the columns of the matrix.

When FEC and interleaving is used, at least one extra byte is required for trellis termination. In addition, the amount of data transmitted over the air must be a multiple of

the size of the interleaver buffer (two bytes). The packet control hardware therefore automatically inserts one or two extra bytes at the end of the packet, so that the total length of the data to be interleaved is an even number. Note that these extra bytes are invisible to the user, as they are removed

before the received packet enters the RX FIFO in a CC1101.

When FEC and interleaving is used, the minimum data payload is 2 bytes in fixed and variable packet length mode.

**Figure 15: General Principle of Matrix Interleaving**

## 16 Radio Control

**Figure 16: Radio Control State Diagram**

CC1150 has a built-in state machine that is used to switch between different operations states (modes). The change of state is done

either by using command strobes or by internal events such as TX FIFO underflow.

A simplified state diagram, together with typical usage and current consumption, is shown in Figure 7 on page 17. The complete radio control state diagram is shown in Figure

## 16.1 Power on Start-up Sequence

When the power supply is turned on, the system must be reset. This is achieved by one of the two sequences described below, i.e. Automatic power-on reset or manual reset. After the automatic power-on reset or manual reset it is also recommended to change the signal that is output on the GDO0 pin. The default setting is to output a clock signal with a frequency of  $CLK\_XOSC/192$ , but to optimize performance in TX, an alternative GDO setting should be selected from the settings found in Table 24 on page 38.

### 16.1.1 Automatic POR

A power-on reset circuit is included in the CC1150. The minimum requirements stated in Section 4.7 must be followed for the power-on reset to function properly. The internal power-up sequence is completed when CHIP\_RDYn goes low. CHIP\_RDYn is observed on the S0 pin after CSn is pulled low. See Section 10.1 for more details on CHIP\_RDYn.

When the CC1150 reset is completed the chip will be in the IDLE state and the crystal oscillator running. If the chip has had sufficient time for the crystal oscillator and voltage regulator to stabilize after the power-on-reset, the S0 pin will go low immediately after taking CSn low. If CSn is taken low before reset is completed the S0 pin will first go high, indicating that the crystal oscillator and voltage regulator is not stabilized, before going low as shown in Figure 17.

Figure 17: Power-on Reset

## 16.2 Crystal Control

The crystal oscillator is automatically turned on when CSn goes low. It will be turned off if the SXOFF or SPWD command strobes are issued; the state machine then goes to XOFF or

16. The numbers refer to the state number readable in the MARCSTATE status register. This functionality is primarily for test purposes.

### 16.1.2 Manual Reset

The other global reset possibility on CC1150 is the SRES command strobe. By issuing this strobe, all internal registers and states are set to the default, IDLE state. The power-up sequence is as follows (see Figure 18):

- Set SCLK = 1 and SI = 0.
- Strobe CSn low / high. Make sure to hold CSn high for at least 40  $\mu$ s relative to pulling CSn low.
- Pull CSn low and wait for S0 to go low (CHIP\_RDYn).
- Issue the SRES strobe on the SI line.
- When S0 goes low again, reset is complete and the chip is in the IDLE state.

Figure 18: Power-up with SRES

Note that the above reset procedure is only required just after the power supply is first turned on. If the user wants to reset the CC1150 after this, it is only necessary to issue an SRES command strobe.

It is recommended to always send a SRES command strobe on the SPI interface after power-on even though power-on reset is used.

SLEEP respectively. This can only be done from IDLE state. The XOSC will be turned off when CSn is released (goes high). The XOSC will be automatically turned on again when

CSn goes low. The state machine will then go to the IDLE state. The S0 pin on the SPI interface must be pulled low before the SPI interface is ready to be used; as described in Section 10.1 on page 19.

## 16.3 Voltage Regulator Control

The voltage regulator to the digital core is controlled by the radio controller. When the chip enters the SLEEP state, which is the state with the lowest current consumption, the voltage regulator is disabled. This occurs after CSn is released when a SPWD command strobe has been sent on the SPI interface. The chip is then in the SLEEP state. Setting CSn low again will turn on the regulator and crystal

Crystal oscillator start-up time depends on crystal ESR and load capacitances. The electrical specification for the crystal oscillator can be found in section 4.3 on page 8.

oscillator and make the chip enter the IDLE state.

On the *CC1150*, all register values (with the exception of the MCSM0.PO\_TIMEOUT field) are lost in the SLEEP state. After the chip gets back to the IDLE state, the registers will have default (reset) contents and must be reprogrammed over the SPI interface.

## 16.4 Active Mode

The active transmit mode is activated by the MCU by using the STX command strobe.

The frequency synthesizer must be calibrated regularly. *CC1150* has one manual calibration option (using the SCAL strobe), and three automatic calibration options, controlled by the MCSM0.FS\_AUTOCAL setting:

- Calibrate when going from IDLE to TX (or FSTXON)
- Calibrate when going from TX to IDLE
- Calibrate every fourth time when going from TX to IDLE

The calibration takes a constant number of XOSC cycles; see Table 20 for timing details. When TX is active, the chip will remain in the

TX state until the current packet has been successfully transmitted. Then the state will change as indicated by the MCSM1.TXOFF\_MODE setting. The possible destinations are:

- IDLE
- FSTXON: Frequency synthesizer on and ready at the TX frequency. Activate TX with STX.
- TX: Start sending preambles

The SIDLE command strobe can always be used to force the radio controller to go to the IDLE state. Note that if the radio goes from TX to IDLE by issuing an SIDLE strobe, the automatic calibration-when-going-from-TX-to-IDLE will not be performed.

## 16.5 Timing

The radio controller controls most timing in *CC1150*, such as synthesizer calibration and PLL lock. Table 20 shows timing in crystal clock cycles for key state transitions. Timing from IDLE to TX is constant, dependent on the auto calibration setting. The calibration time is constant 18739 clock periods. Power on time

and XOSC start-up times are variable, but within the limits stated in Table 6. Note that in a frequency hopping spread spectrum or a multi-channel protocol the calibration time can be reduced from 721  $\mu$ s to approximately 150  $\mu$ s. This is explained in section 24.2.

| Description                         | XOSC periods | 26 MHz crystal |
|-------------------------------------|--------------|----------------|
| Idle to TX/FSTXON, no calibration   | 2298         | 88.4 $\mu$ s   |
| Idle to TX/FSTXON, with calibration | ~21037       | 809 $\mu$ s    |
| TX to IDLE, no calibration          | 2            | 0.1 $\mu$ s    |
| TX to IDLE, including calibration   | ~18739       | 721 $\mu$ s    |
| Manual calibration                  | ~18739       | 721 $\mu$ s    |

Table 20: State Transition Timing

## 17 Data FIFO

The CC1150 contains a 64 byte FIFO for data to be transmitted. The SPI interface is used for writing to the TX FIFO. Section 10.5 contains details on the SPI FIFO access. The FIFO controller will detect underflow in the TX FIFO.

When writing to the TX FIFO, it is the responsibility of the MCU to avoid TX FIFO overflow. This will not be detected by the CC1150. A TX FIFO overflow will result in an error in the TX FIFO content.

| FIFO_THR  | Bytes in TX FIFO |
|-----------|------------------|
| 0 (0000)  | 61               |
| 1 (0001)  | 57               |
| 2 (0010)  | 53               |
| 3 (0011)  | 49               |
| 4 (0100)  | 45               |
| 5 (0101)  | 41               |
| 6 (0110)  | 37               |
| 7 (0111)  | 33               |
| 8 (1000)  | 29               |
| 9 (1001)  | 25               |
| 10 (1010) | 21               |
| 11 (1011) | 17               |
| 12 (1100) | 13               |
| 13 (1101) | 9                |
| 14 (1110) | 5                |
| 15 (1111) | 1                |

Table 21: FIFO\_THR Settings and the corresponding FIFO Thresholds

The chip status byte that is available on the S0 pin while transferring the SPI address contains the fill grade of the TX FIFO. Section 10.1 on page 19 contains more details on this.

The number of bytes in the TX FIFO can also be read from the TXBYTES.NUM\_TXBYTES status register.

The 4-bit FIFOTH.R.FIFO\_THR setting is used to program the FIFO threshold point. Table 21

lists the 16 FIFO\_THR settings and the corresponding thresholds for the TX FIFO.

Figure 19: Example of FIFO at Threshold

A flag will assert when the number of bytes in the FIFO is equal to or higher than the programmed threshold. The flag is used to generate the FIFO status signals that can be viewed on the GDO pins (see section 22 on page 37).

Figure 19 shows the number of bytes in the TX FIFO when the threshold flag toggles, in the case of FIFO\_THR=13. Figure 20 shows the flag as the FIFO is filled above the threshold, and then drained below.

Figure 20: FIFO\_THR=13 vs. Number of Bytes in FIFO

## 18 Frequency Programming

The frequency programming in *CC1150* is designed to minimize the programming needed in a channel-oriented system.

To set up a system with channel numbers, the desired channel spacing is programmed with the `MDMCFG0.CHANSPC_M` and `MDMCFG1.CHANSPC_E` registers. The channel spacing registers are mantissa and exponent respectively.

The base or start frequency is set by the 24 bit frequency word located in the `FREQ2`, `FREQ1` and `FREQ0` registers. This word will typically be set to the centre of the lowest channel frequency that is to be used.

The desired channel number is programmed with the 8-bit channel number register, `CHANNR.CHAN`, which is multiplied by the channel offset. The resultant carrier frequency is given by:

$$f_{\text{carrier}} = \frac{f_{\text{XOSC}}}{2^{16}} \cdot \left( \text{FREQ} + \text{CHAN} \cdot \left( (256 + \text{CHANSPC\_M}) \cdot 2^{\text{CHANSPC\_E}-2} \right) \right)$$

With a 26 MHz crystal the maximum channel spacing is 405 kHz. To get e.g. 1 MHz channel spacing on solution is to use 333 kHz channel spacing and select each third channel in `CHANNR.CHAN`.

If any frequency programming register is altered when the frequency synthesizer is running, the synthesizer may give an undesired response. Hence, the frequency programming should only be updated when the radio is in the IDLE state.

## 19 VCO

The VCO is completely integrated on-chip.

### 19.1 VCO and PLL Self-Calibration

The VCO characteristics will vary with temperature and supply voltage changes, as well as the desired operating frequency. In order to ensure reliable operation, *CC1150* includes frequency synthesizer self-calibration circuitry. This calibration should be done regularly, and must be performed after turning on power and before using a new frequency (or channel). The number of XOSC cycles for completing the PLL calibration is given in Table 20 on page 33.

The calibration can be initiated automatically or manually. The synthesizer can be automatically calibrated each time the synthesizer is turned on, or each time the synthesizer is turned off. This is configured with the `MCSM0.FS_AUTOCAL` register setting.

In manual mode, the calibration is initiated when the `SCAL` command strobe is activated in the IDLE mode.

The calibration values are not maintained in sleep mode. Therefore, the *CC1150* must be recalibrated after reprogramming the configuration registers when the chip has been in the SLEEP state.

To check that the PLL is in lock the user can program register `IOCFGx.GDOx_CFG` to 0x0A and use the lock detector output available on the `GDOx` pin as an interrupt for the MCU ( $x = 0, 1$  or  $2$ ). A positive transition on the `GDOx` pin means that the PLL is in lock. As an alternative the user can read register `FSCAL1`. The PLL is in lock if the register content is different from 0x3F. See more information in the *CC1150* Errata Notes [8].

For more robust operation the source code could include a check so that the PLL is recalibrated until PLL lock is achieved if the PLL does not lock the first time.

## 20 Voltage Regulators

CC1150 contains several on-chip linear voltage regulators, which generate the supply voltage needed by low-voltage modules. These voltage regulators are invisible to the user, and can be viewed as integral parts of the various modules. The user must however make sure that the absolute maximum ratings and required pin voltages in Table 1 and Table 11 are not exceeded.

Setting the CSn pin low turns on the voltage regulator to the digital core and start the crystal oscillator. The S0 pin on the SPI interface must go low before the first positive

edge on the SCLK (setup time is s given in Table 15).

If the chip is programmed to enter power-down mode (SPWD strobe issued), the power will be turned off after CSn goes high. The power and crystal oscillator will be turned on again when CSn goes low.

The voltage regulator for the digital core requires one external decoupling capacitor. The voltage regulator output should only be used for driving the CC1150.

## 21 Output Power Programming

The RF output power level from the device has two levels of programmability, as illustrated in Figure 21. Firstly, the special PATABLE register can hold up to eight user selected output power settings. Secondly, the 3-bit FREND0.PA\_POWER value selects the PATABLE entry to use. This two-level functionality provides flexible PA power ramp up and ramp down at the start and end of transmission, as well as ASK modulation shaping. In each case, all the PA power settings in the PATABLE from index 0 up to the FREND0.PA\_POWER value are used.

The power ramping at the start and at the end of a packet can be turned off by setting FREND0.PA\_POWER to zero and then programming the desired output power to index 0 in the PATABLE.

If OOK modulation is used, the logic 0 and logic 1 power levels shall be programmed to index 0 and 1 respectively.

Table 22 contains recommended PATABLE settings for various output levels and frequency bands. DN012 [3] gives complete tables for the different frequency bands. Using PA settings from 0x61 to 0x6F is not recommended. Table 23 contains output power and current consumption for default PATABLE setting (0xC6).

PATABLE must be programmed in burst mode if you want to write to other entries than PATABLE[0]. See section 10.6 on page 22 for PATABLE programming details.

Figure 21: PA\_POWER and PATABLE

|                    | 315 MHz |                                | 433 MHz |                                | 868 MHz |                                | 915 MHz |                                |

Table 23: Output Power and Current Consumption for Default PATABLE Setting

### 21.1 Shaping and PA Ramping

With ASK modulation, up to eight power settings are used for shaping. The modulator contains a counter that counts up when transmitting a one and down when transmitting a zero. The counter counts at a rate equal to 8 times the symbol rate. The counter saturates at `FREND0.PA_POWER` and 0 respectively. This counter value is used as an index for a lookup in the power table. Thus, in order to

utilize the whole table, `FREND0.PA_POWER` should be 7 when ASK is active. The shaping of the ASK signal is dependent on the configuration of the PATABLE. Figure 22 shows some examples of ASK shaping. Note that the OOK/ASK pulse shaping feature on the *CC1150* is only supported for output power levels below -1 dBm.

Figure 22: Shaping of ASK Signal

## 22 General Purpose / Test Output Control Pins

The two digital output pins GD00 and GD01 are general control pins. Their functions are programmed by `IOCFG0.GD00_CFG` and `IOCFG1.GD01_CFG` respectively. Table 24 shows the different signals that can be monitored on the GDO pins. These signals can be used as an interrupt to the MCU.

GD01 is the same pin as the S0 pin on the SPI interface, thus the output programmed on this pin will only be valid when CSn is high. The default value for GD01 is 3-stated, which is useful when the SPI interface is shared with other devices.

The default value for GD00 is a 125 - 146 kHz clock output (XOSC frequency divided by 192). Since the XOSC is turned on at power-on-reset, this can be used to clock the MCU in systems with only one crystal. When the MCU is up and running it can change the clock frequency by writing to `IOCFG0.GD00_CFG`.

An on-chip analog temperature sensor is enabled by writing the value 128 (0x80h) to the `IOCFG0.GD00_CFG` register. The voltage on the GD00 pin is then proportional to temperature. See section 4.5 on page 9 for temperature sensor specifications.

| GDOx_CFG[5:0] | Description                                                                                                                                                                                                            |

| 58 (0x3A)     | CLK_XOSC/32                                                                                                                                                                                                            |
| 59 (0x3B)     | CLK_XOSC/48                                                                                                                                                                                                            |
| 60 (0x3C)     | CLK_XOSC/64                                                                                                                                                                                                            |
| 61 (0x3D)     | CLK_XOSC/96                                                                                                                                                                                                            |
| 62 (0x3E)     | CLK_XOSC/128                                                                                                                                                                                                           |
| 63 (0x3F)     | CLK_XOSC/192                                                                                                                                                                                                           |

Note: There are 2 GDO pins, but only one CLK\_XOSC/n can be selected as an output at any time. If CLK\_XOSC/n is to be monitored on one of the GDO pins, the other GDO pin must be configured to values less than 0x30. The GDO0 default value is CLK\_XOSC/192.

To optimize RF performance, these signals should not be used while the radio is in TX mode.

Table 24: GDO signal selection(x = 0 or 1)

## 23 Asynchronous and Synchronous Serial Operation

Several features and modes of operation have been included in the *CC1150* to provide backward compatibility with previous Chipcon products and other existing RF communication systems. For new systems, it is recommended

to use the built-in packet handling features, as they can give more robust communication, significantly offload the microcontroller and simplify software development.

### 23.1 Asynchronous Serial Operation

For backward compatibility with systems already using the asynchronous data transfer from other Chipcon products, asynchronous transfer is also included in *CC1150*.

When asynchronous transfer is enabled, several of the support mechanisms for the MCU that are included in *CC1150* will be disabled, such as packet handling hardware, buffering in the FIFO and so on. The asynchronous transfer mode does not allow the use of the data whitener, interleaver and FEC, and it is not possible to use Manchester encoding. MSK is not supported for asynchronous transfer.

Setting `PKTCTRL0.PKT_FORMAT` to 3 enables asynchronous transparent (serial) mode. In TX, the `GD00` pin is used for data input (TX data).

The MCU must control start and stop of transmit with the STX and SIDLE strobes.

The *CC1150* modulator samples the level of the asynchronous input 8 times faster than the programmed data rate. The timing requirement for the asynchronous stream is that the error in the bit period must be less than one eighth of the programmed data rate.

### 23.2 Synchronous Serial Operation

Setting `PKTCTRL0.PKT_FORMAT` to 1 enables synchronous serial operation mode. In this operational mode the data must be NRZ encoded (`MDMCFG2.MANCHESTER_EN=0`). In synchronous serial operation mode, data is transferred on a two wire serial interface. The *CC1150* provides a clock that is used to set up new data on the data input line. Data input (TX data) is the `GD00` pin. This pin will automatically be configured as an input when TX is active. The TX latency is 8 bits.

Preamble and sync word insertion may or may not be active, dependent on the sync mode set by the `MDMCFG3.SYNC_MODE`.

If preamble and sync word is disabled, all other packet handler features and FEC should also be disabled. The MCU must then handle preamble and sync word insertion in software.

If preamble and sync word insertion is left on, all packet handling features and FEC can be used. When using the packet handling features synchronous serial mode, the *CC1150* will insert the preamble and sync word and the MCU will only provide the data payload. This is equivalent to the recommended FIFO operation mode.

## 24 System considerations and Guidelines

### 24.1 SRD Regulations

International regulations and national laws regulate the use of radio receivers and transmitters. Short Range Devices (SRDs) for license free operation below 1 GHz are usually operated in the 315 MHz, 433 MHz, 868 MHz or 915 MHz frequency bands. The *CC1150* is specifically designed for such use with its 300-348 MHz, 400-464 MHz and 800-928 MHz operating ranges. The most important regulations when using the *CC1150* in the 315

MHz, 433 MHz, 868 MHz or 915 MHz frequency bands are EN 300 220 (Europe) and FCC CFR47 part 15 (USA). A summary of the most important aspects of these regulations can be found in AN001 [10].

Please note that compliance with regulations is dependent on complete system performance. It is the end product manufacturer's

responsibility to ensure that the system

complies with regulations.

## 24.2 Frequency Hopping and Multi-Channel Systems

The 315 MHz, 433 MHz, 868 MHz or 915 MHz bands are shared by many systems both in industrial, office and home environments. It is therefore recommended to use frequency hopping spread spectrum (FHSS) or a multi-channel protocol because the frequency diversity makes the system more robust with respect to interference from other systems operating in the same frequency band. FHSS also combats multipath fading.

*CC1150* is highly suited for FHSS or multi-channel systems due to its agile frequency synthesizer and effective communication interface. Using the packet handling support and data buffering is also beneficial in such systems as these features will significantly offload the host controller.

Charge pump current, VCO current and VCO capacitance array calibration data is required for each frequency when implementing frequency hopping for *CC1150*. There are 3 ways of obtaining the calibration data from the chip:

- 1) Frequency hopping with calibration for each hop. The PLL calibration time is approximately 720  $\mu$ s. The blanking interval between each frequency hop is then approximately 810  $\mu$ s.
- 2) Fast frequency hopping without calibration for each hop can be done by calibrating each frequency at startup and saving the resulting FSCAL3, FSCAL2 and FSCAL1 register values in MCU memory. The VCO capacitance calibration FSCAL1 register value must be found for each RF frequency to be used. The VCO current calibration value and the charge pump current calibration value available in FSCAL2 and FSCAL3 respectively are not dependent on the RF frequency, so the same value can therefore be used for all RF frequencies for these two registers. Between each frequency hop, the calibration process

can then be replaced by writing the FSCAL3, FSCAL2 and FSCAL1 register values that corresponds to the next RF frequency. The PLL turn on time is approximately 90  $\mu$ s. The blanking interval between each frequency hop is then approximately 90  $\mu$ s.

- 3) Run calibration on a single frequency at startup. Next write 0 to FSCAL3[5:4] to disable the charge pump calibration. After writing to FSCAL3[5:4], strobe STX with `MCSM0.FS_AUTOCAL=1` for each new frequency hop. That is, VCO current and VCO capacitance calibration is done, but not charge pump current calibration. When charge pump current calibration is disabled the calibration time is reduced from approximately 720  $\mu$ s to approximately 150  $\mu$ s. The blanking interval between each frequency hop is then approximately 240  $\mu$ s.

There is a trade off between blanking time and memory space needed for storing calibration data in non-volatile memory. Solution 2) above gives the shortest blanking interval, but requires more memory space to store calibration values. This solution also requires that the supply voltage and temperature do not vary much in order to have a robust solution. Solution 3) gives approximately 570  $\mu$ s smaller blanking interval than solution 1).

The recommended settings for `TEST0.VCO_SEL_CAL_EN` change with frequency. This means that one should always use SmartRF Studio [11] to get the correct settings for a specific frequency before doing a calibration, regardless of which calibration method is being used. It must be noted that the content of the *CC1150* is not retained in SLEEP state, and thus it is necessary to write to the TEST0 register, along with other registers, when returning from the SLEEP state and initiating calibrations.

## 24.3 Wideband Modulation not using Spread Spectrum

Digital modulation systems under FFC part 15.247 include FSK and GFSK modulation. A maximum peak output power of 1W (+30 dBm) is allowed if the 6 dB bandwidth of the modulated signal exceeds 500 kHz. In addition, the peak power spectral density conducted to the antenna shall not be greater than +8 dBm in any 3 kHz band.

Operating at high data rates and frequency deviation the *CC1150* is suited for systems targeting compliance with digital modulation system as defined by FFC part 15.247. An external power amplifier is needed to increase the output above +10 dBm. Please refer to DN006 [5] for further details concerning wideband modulation and *CC1150*.

## 24.4 Data Burst Transmissions

The high maximum data rate of *CC1150* opens up for burst transmissions. A low average data rate link (e.g. 10 kBaud), can be realized using a higher over-the-air data rate. Buffering the data and transmitting in bursts at high data rate (e.g. 500 kBaud) will reduce the time in

active mode, and hence also reduce the average current consumption significantly. Reducing the time in active mode will reduce the likelihood of collisions with other systems in the same frequency range.

## 24.5 Continuous Transmissions

In data streaming applications the *CC1150* opens up for continuous transmissions at 500 kBaud effective data rate. As the modulation is done with a closed loop PLL, there is no

limitation in the length of a transmission (open loop modulation used in some transceivers often prevents this kind of continuous data streaming and reduces the effective data rate).

## 24.6 Low Cost Systems

As the *CC1150* provides 500 kBaud multi-channel performance without any external filters, a very low cost system can be made. A HC-49 type SMD crystal is used in the CC1150EM reference design ([1] and [1]).

Note that the crystal package strongly influences the price. In a size constrained PCB design a smaller, but more expensive, crystal may be used.

## 24.7 Battery Operated Systems

In low power applications, the SLEEP state

should be used when the *CC1150* is not active.

## 24.8 Increasing Output Power

In some applications it may be necessary to extend the link range. Adding an external power amplifier is the most effective way of doing this.

The power amplifier should be inserted between the antenna and the balun as shown in Figure 23.

**Figure 23 Block Diagram of *CC1150* Usage with External Power Amplifier**

## 25 Configuration Registers

The configuration of *CC1150* is done by programming 8-bit registers. The configuration data based on selected system parameters are most easily found by using the SmartRF Studio [11] software. Complete descriptions of the registers are given in the following tables. After chip reset, all the registers have default values as shown in the tables. The optimum register setting might differ from the default value. After a reset, all registers that shall be different from the default value therefore needs to be programmed through the SPI interface.

There are 9 Command Strobe Registers, listed in Table 25. Accessing these registers will initiate the change of an internal state or mode. There are 29 normal 8-bit Configuration Registers, listed in Table 26. Many of these registers are for test purposes only, and need not be written for normal operation of *CC1150*.

There are also 6 Status registers, which are listed in Table 27. These registers, which are read-only, contain information about the status of *CC1150*.

The TX FIFO is accessed through one 8-bit register. Only write operations are allowed to the TX FIFO.

During the address transfer and while writing to a register or the TX FIFO, a status byte is returned. This status byte is described in Table 16 on page.20.

Table 28 summarizes the SPI address space. Registers that are only defined on the *CC1101* transceiver are also listed. *CC1101* and *CC1150* are register compatible, but registers and fields only implemented in the transceiver always contain 0 in *CC1150*.

The address to use is given by adding the base address to the left and the burst and read/write bits on the top. Note that the burst bit has different meaning for base addresses above and below 0x2F.

| Address | Strobe Name | Description                                                                                                                                                             |
|---------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x30    | SRES        | Reset chip.                                                                                                                                                             |
| 0x31    | SFSTXON     | Enable and calibrate frequency synthesizer (if MCSM0 . FS_AUTOCAL=1).                                                                                                   |
| 0x32    | SXOFF       | Turn off crystal oscillator.                                                                                                                                            |
| 0x33    | SCAL        | Calibrate frequency synthesizer and turn it off (enables quick start). SCAL can be strobed in IDLE state without setting manual calibration mode (MCSM0 . FS_AUTOCAL=0) |
| 0x35    | STX         | Enable TX. Perform calibration first if MCSM0 . FS_AUTOCAL=1.                                                                                                           |
| 0x36    | SIDLE       | Exit TX and turn off frequency synthesizer.                                                                                                                             |
| 0x39    | SPWD        | Enter power down mode when CSN goes high.                                                                                                                               |
| 0x3B    | SFTX        | Flush the TX FIFO buffer.                                                                                                                                               |
| 0x3D    | SNOP        | No operation. May be used to pad strobe commands to two bytes for simpler software.                                                                                     |

**Table 25: Command Strobes**

| Address | Register | Description                                    | Details on page number |
|---------|----------|------------------------------------------------|------------------------|
| 0x01    | IOCFG1   | GD01 output pin configuration                  | 45                     |

**Table 28: SPI Address Space** (greyed text: not implemented on *CC1150* thus only valid for the transceiver version (*CC1101*))

## 25.1 Configuration Register Details

### 0x01: IOCFG1 – GD01 output pin configuration

| Bit | Field Name    | Reset     | R/W | Description                                                    |
|-----|---------------|-----------|-----|----------------------------------------------------------------|
| 7   | GDO_DS        | 0         | R/W | Set high (1) or low (0) output drive strength on the GDO pins. |
| 6   | GD01_INV      | 0         | R/W | Invert output, i.e. select active low (1) / high (0).          |
| 5:0 | GD01_CFG[5:0] | 46 (0x2E) | R/W | Default is tri-state (See Table 24 on page 38).                |

### 0x02: IOCFG0 – GD00 output pin configuration

| Bit | Field Name         | Reset     | R/W | Description                                                                                                                                                    |
|-----|--------------------|-----------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | TEMP_SENSOR_ENABLE | 0         | R/W | Enable analog temperature sensor. Write 0 in all other register bits when using temperature sensor.                                                            |
| 6   | GD00_INV           | 0         | R/W | Invert output, i.e. select active low (1) / high (0).                                                                                                          |
| 5:0 | GD00_CFG[5:0]      | 63 (0x3F) | R/W | Default is CLK_XOSC/192 (See Table 24 on page 38).<br>It is recommended to disable the clock output during initialization in order to optimize RF performance. |

### 0x03: FIFOTHR – FIFO threshold

| Bit       | Field Name       | Reset    | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |         |                  |          |    |          |    |          |    |          |    |          |    |          |    |          |    |          |    |          |    |          |    |           |    |           |    |           |    |           |   |           |   |           |   |
|-----------|------------------|----------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|------------------|----------|----|----------|----|----------|----|----------|----|----------|----|----------|----|----------|----|----------|----|----------|----|----------|----|-----------|----|-----------|----|-----------|----|-----------|---|-----------|---|-----------|---|
| 7:4       | Reserved         | 0        | R/W | Write 0 for compatibility with possible future extensions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |         |                  |          |    |          |    |          |    |          |    |          |    |          |    |          |    |          |    |          |    |          |    |           |    |           |    |           |    |           |   |           |   |           |   |
| 3:0       | FIFO_THR[3:0]    | 7 (0x07) | R/W | Set the threshold for the TX FIFO. The threshold is exceeded when the number of bytes in the FIFO is equal to or higher than the threshold value. <table><tr><th>Setting</th><th>Bytes in TX FIFO</th></tr><tr><td>0 (0000)</td><td>61</td></tr><tr><td>1 (0001)</td><td>57</td></tr><tr><td>2 (0010)</td><td>53</td></tr><tr><td>3 (0011)</td><td>49</td></tr><tr><td>4 (0100)</td><td>45</td></tr><tr><td>5 (0101)</td><td>41</td></tr><tr><td>6 (0110)</td><td>37</td></tr><tr><td>7 (0111)</td><td>33</td></tr><tr><td>8 (1000)</td><td>29</td></tr><tr><td>9 (1001)</td><td>25</td></tr><tr><td>10 (1010)</td><td>21</td></tr><tr><td>11 (1011)</td><td>17</td></tr><tr><td>12 (1100)</td><td>13</td></tr><tr><td>13 (1101)</td><td>9</td></tr><tr><td>14 (1110)</td><td>5</td></tr><tr><td>15 (1111)</td><td>1</td></tr></table> | Setting | Bytes in TX FIFO | 0 (0000) | 61 | 1 (0001) | 57 | 2 (0010) | 53 | 3 (0011) | 49 | 4 (0100) | 45 | 5 (0101) | 41 | 6 (0110) | 37 | 7 (0111) | 33 | 8 (1000) | 29 | 9 (1001) | 25 | 10 (1010) | 21 | 11 (1011) | 17 | 12 (1100) | 13 | 13 (1101) | 9 | 14 (1110) | 5 | 15 (1111) | 1 |

| 3 (11)  | Reserved                                                                            |       |     |                                                                                                                                                                                                                                                                                                                                                                                                                                 |         |                             |        |                                                            |        |                                                                                     |        |                                                                             |        |                                                |

**0x09: ADDR – Device address**

| Bit | Field Name           | Reset | R/W | Description                                                                                   |
|-----|----------------------|-------|-----|-----------------------------------------------------------------------------------------------|
| 7:0 | DEVICE_ADDRESS [7:0] | 0     | R/W | Address used for packet filtration. Optional broadcast addresses are 0 (0x00) and 255 (0xFF). |

**0x0A: CHANNR – Channel number**

| Bit | Field Name | Reset | R/W | Description                                                                                                            |
|-----|------------|-------|-----|------------------------------------------------------------------------------------------------------------------------|
| 7:0 | CHAN[7:0]  | 0     | R/W | The 8-bit unsigned channel number, which is multiplied by the channel spacing setting and added to the base frequency. |

**0x0D: FREQ2 – Frequency control word, high byte**

| Bit | Field Name  | Reset     | R/W | Description                                                                                                                                                         |
|-----|-------------|-----------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:6 | FREQ[23:22] | 0         | R   | FREQ[23:22] is always 0 (the FREQ2 register is less than 36 with 26 MHz or higher crystal frequency).                                                               |
| 5:0 | FREQ[21:16] | 30 (0x1E) | R/W | FREQ[23:0] is the base frequency for the frequency synthesiser in increments of $F_{XOSC}/2^{16}$ .<br><br>$f_{carrier} = \frac{f_{XOSC}}{2^{16}} \cdot FREQ[23:0]$ |

**0x0E: FREQ1 – Frequency control word, middle byte**

| Bit | Field Name | Reset      | R/W | Description          |
|-----|------------|------------|-----|----------------------|
| 7:0 | FREQ[15:8] | 196 (0xC4) | R/W | Ref. FREQ2 register. |

**0x0F: FREQ0 – Frequency control word, low byte**

| Bit | Field Name | Reset      | R/W | Description          |
|-----|------------|------------|-----|----------------------|
| 7:0 | FREQ[7:0]  | 236 (0xEC) | R/W | Ref. FREQ2 register. |

**0x10: MDMCFG4 – Modulator configuration**

| Bit | Field Name   | Reset     | R/W | Description                                     |
|-----|--------------|-----------|-----|-------------------------------------------------|
| 7:4 | Reserved     | 8 (0x08)  | R0  | Defined on the transceiver version (CC1101).    |
| 3:0 | DRATE_E[3:0] | 12 (0x0C) | R/W | The exponent of the user specified symbol rate. |

**0x11: MDMCFG3 – Modulator configuration**

| Bit | Field Name   | Reset     | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----|--------------|-----------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0 | DRATE_M[7:0] | 34 (0x22) | R/W | <p>The mantissa of the user specified symbol rate. The symbol rate is configured using an unsigned, floating-point number with 9-bit mantissa and 4-bit exponent. The 9<sup>th</sup> bit is a hidden '1'. The resulting data rate is:</p> $R_{DATA} = \frac{(256 + DRATE\_M) \cdot 2^{DRATE\_E}}{2^{28}} \cdot f_{XOSC}$ <p>The default values give a data rate of 115.051 kBaud (closest setting to 115.2 kBaud), assuming a 26.0 MHz crystal.</p> |

## 0x12: MDMCFG2 – Modulator configuration

| Bit     | Field Name                                      | Reset | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |         |                          |         |                       |         |                               |         |                               |         |                               |         |                                                 |         |                                       |         |                                       |         |                                       |

| 7:0 | CHANSPC_M[7:0] | 248 (0xF8) | R/W | 8-bit mantissa of channel spacing (initial 1 assumed). The channel spacing is multiplied by the channel number CHAN and added to the base frequency. It is unsigned and has the format:<br><br>$\Delta f_{CHANNEL} = \frac{f_{XOSC}}{2^{18}} \cdot (256 + CHANSPC\_M) \cdot 2^{CHANSPC\_E} \cdot CHAN$<br>The default values give 199.951 kHz channel spacing (the closest setting to 200 kHz), assuming 26.0 MHz crystal frequency. |

| 7:6 |             |           | R0  | Not Used.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 5:0 | FSCAL1[5:0] | 32 (0x20) | R/W | Frequency synthesizer calibration result register. Capacitor array setting for VCO coarse tuning.<br>Fast frequency hopping without calibration for each hop can be done by calibrating upfront for each frequency and saving the resulting FSCAL3, FSCAL2 and FSCAL1 register values. Between each frequency hop, calibration can be replaced by writing the FSCAL3, FSCAL2 and FSCAL1 register values corresponding to the next RF frequency. |

**0x26: FSCAL0 – Frequency synthesizer calibration**

| Bit | Field Name  | Reset     | R/W | Description                                                                                                                 |
|-----|-------------|-----------|-----|-----------------------------------------------------------------------------------------------------------------------------|
| 7   | Reserved    |           | R0  | Not Used.                                                                                                                   |
| 6:0 | FSCAL0[6:0] | 13 (0x0D) | R/W | Frequency synthesizer calibration control. The value to use in register field is given by the SmartRF Studio [11] software. |

**0x29: FSTEST – Frequency synthesizer calibration control**

| Bit | Field Name  | Reset     | R/W | Description                                   |
|-----|-------------|-----------|-----|-----------------------------------------------|
| 7:0 | FSTEST[7:0] | 87 (0x57) | R/W | For test only. Do not write to this register. |

**0x2A: PTEST – Production test**

| Bit | Field Name | Reset      | R/W | Description                                                                                                                                                                                                                    |
|-----|------------|------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0 | PTEST[7:0] | 127 (0x7F) | R/W | Writing 0xBF to this register makes the on-chip temperature sensor available in the IDLE state. The default 0x7F value should then be written back before leaving the IDLE state. Other use of this register is for test only. |

**0x2C: TEST2 – Various test settings**

| Bit | Field Name | Reset | R/W | Description                                                                     |
|-----|------------|-------|-----|---------------------------------------------------------------------------------|
| 7:0 | TEST2[7:0] |       | R/W | The value to use in this register is given by the SmartRF Studio [11] software. |

**0x2D: TEST1 – Various test settings**

| Bit | Field Name | Reset     | R/W | Description                                                                     |
|-----|------------|-----------|-----|---------------------------------------------------------------------------------|
| 7:0 | TEST1[7:0] | 49 (0x21) | R/W | The value to use in this register is given by the SmartRF Studio [11] software. |

**0x2E: TEST0 – Various test settings**

| Bit | Field Name     | Reset   | R/W | Description                                                                                                                    |
|-----|----------------|---------|-----|--------------------------------------------------------------------------------------------------------------------------------|
| 7:2 | TEST0[7:2]     | 2(0x02) | R/W | The value to use in this register is given by the SmartRF Studio [11] software.                                                |
| 1   | VCO_SEL_CAL_EN | 1       | R/W | Enable VCO selection calibration stage when 1. The value to use in this register is given by the SmartRF Studio [11] software. |
| 0   | TEST0[0]       | 1       | R/W | The value to use in this register is given by the SmartRF Studio [11] software.                                                |

## 25.2 Status register details

**0x30 (0xF0): PARTNUM – Chip ID**

| Bit | Field Name   | Reset    | R/W | Description       |
|-----|--------------|----------|-----|-------------------|
| 7:0 | PARTNUM[7:0] | 2 (0x02) | R   | Chip part number. |

**0x31 (0xF1): VERSION – Chip ID**

| Bit | Field Name   | Reset    | R/W | Description          |
|-----|--------------|----------|-----|----------------------|
| 7:0 | VERSION[7:0] | 4 (0x04) | R   | Chip version number. |

**0x35 (0xF5): MARCSTATE – Main Radio Control State Machine state**

| Bit       | Field Name      | Reset                      | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |       |            |                            |          |       |       |          |      |      |          |      |      |          |          |        |          |          |        |          |        |        |          |       |           |          |       |           |          |          |           |          |         |          |           |         |          |           |     |     |           |        |           |           |     |     |           |     |     |           |     |     |           |     |     |           |     |     |           |        |        |           |    |    |           |        |    |           |     |     |           |              |              |

**0x38 (0xF8): PKTSTATUS – Current GDOx status**

| Bit | Field Name | Reset | R/W | Description                                                                                                                                                                                                               |
|-----|------------|-------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:2 | Reserved   |       | R0  | Defined on the transceiver version ( <i>CC1101</i> ).                                                                                                                                                                     |
| 1   |            |       | R0  | Not Used.                                                                                                                                                                                                                 |
| 0   | GD00       |       | R   | Current GD00 value. Note: the reading gives the non-inverted value irrespective what IOCFG0 . GD00_INV is programmed to.<br><br>It is not recommended to check for PLL lock by reading PKTSTATUS[0] with GD00_CFG = 0x0A. |

**0x39 (0xF9): VCO\_VC\_DAC – Current setting from PLL calibration module**

| Bit | Field Name      | Reset | R/W | Description                     |
|-----|-----------------|-------|-----|---------------------------------|
| 7:0 | VCO_VC_DAC[7:0] |       | R   | Status registers for test only. |

**0x3A (0xFA): TXBYTES – Underflow and number of bytes**

| Bit | Field Name       | Reset | R/W | Description                 |
|-----|------------------|-------|-----|-----------------------------|
| 7   | TXFIFO_UNDERFLOW |       | R   |                             |
| 6:0 | NUM_TXBYTES      |       | R   | Number of bytes in TX FIFO. |

## 26 Package Description (QLP 16)

## 26.1 Recommended PCB layout for package (QLP 16)

**Figure 24: Recommended PCB layout for QLP 16 package**

Note: The figure is an illustration only and not to scale. There are five 10 mil diameter via holes distributed symmetrically in the ground pad under the package. See also the CC1150EM reference design ([1] and [2]).

## 26.2 Soldering information

The recommendations for lead-free reflow in IPC/JEDEC J-STD-020 should be followed.

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) Only one of markings shown within the brackets will appear on the physical device.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

**TAPE AND REEL INFORMATION**

## RST (S-PQFP-N16)

## PLASTIC QUAD FLATPACK

4207803/A 04/06

- NOTES:
- A. All linear dimensions are in millimeters.
  - B. This drawing is subject to change without notice.
  - C. QFN (Quad Flatpack No-Lead) Package configuration.
  -  The package thermal pad must be soldered to the board for thermal and mechanical performance. See the Product Data Sheet for details regarding the exposed thermal pad dimensions.

## THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at [www.ti.com](http://www.ti.com).

The exposed thermal pad dimensions for this package are shown in the following illustration.

Bottom View

Exposed Thermal Pad Dimensions

### NOTES:

All linear dimensions are in millimeters

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.

### TI E2E Community

[e2e.ti.com](http://e2e.ti.com)

## О компании

ООО "ТрейдЭлектроникс" - это оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов. Реализуемая нашей компанией продукция насчитывает более полумиллиона наименований.

Благодаря этому наша компания предлагает к поставке практически не ограниченный ассортимент компонентов как оптовыми, мелкооптовыми партиями, так и в розницу.

Наличие собственной эффективной системы логистики обеспечивает надежную поставку продукции по конкурентным ценам в точно указанные сроки.

Срок поставки со стоков в **Европе и Америке – от 3 до 14 дней.**

Срок поставки из **Азии – от 10 дней.**

Благодаря развитой сети поставщиков, помогаем в поиске и приобретении экзотичных или снятых с производства компонентов.

Предоставляем спец цены на элементы для создания инженерных сэмплов.

**Упорный труд, качественный результат дают нам право быть уверенными в себе и надежными для наших клиентов.**

### **Наша компания это:**

- Гарантия качества поставляемой продукции
- Широкий ассортимент
- Минимальные сроки поставок
- Техническая поддержка
- Подбор комплектации
- Индивидуальный подход
- Гибкое ценообразование

Наша организация особенно сильна в поставках модулей, микросхем, пассивных компонентов, ксайленсах (XC), EPF, EPM и силовой электроники.

Большой выбор предлагаемой продукции, различные виды оплаты и доставки, позволят Вам сэкономить время и получить максимум выгоды от сотрудничества с нами!

## Перечень производителей, продукцию которых мы поставляем на российский рынок

Trade Electronics.ru

гарантия бесперебойности производства и  
качества выпускаемой продукции

С удовольствием будем прорабатывать для Вас поставки всех необходимых компонентов по текущим запросам для скорейшего выявления групп элементов, по которым сотрудничество именно с нашей компанией будет для Вас максимально выгодным!

С уважением,

Менеджер отдела продаж ООО

«Трейд Электроникс»

Шишлаков Евгений
