

## FEATURES

- Stops High Voltage Surges
- Adjustable Output Clamp Voltage
- Overcurrent Protection
- Wide Operation Range: 4V to 80V
- Reverse Input Protection to -60V
- Low 7 $\mu$ A Shutdown Current, LT4356-1
- Adjustable Fault Timer
- Controls N-channel MOSFET
- Shutdown Pin Withstands -60V to 100V
- Fault Output Indication
- Guaranteed Operation to 125°C
- Auxiliary Amplifier for Level Detection Comparator or Linear Regulator Controller
- Available in (4mm  $\times$  3mm) 12-Pin DFN, 10-Pin MSOP or 16-Pin SO Packages

## APPLICATIONS

- Automotive/Avionic Surge Protection
- Hot Swap/Live Insertion
- High Side Switch for Battery Powered Systems
- Intrinsic Safety Applications

## DESCRIPTION

The LT<sup>®</sup>4356 surge stopper protects loads from high voltage transients. It regulates the output during an overvoltage event, such as load dump in automobiles, by controlling the gate of an external N-channel MOSFET. The output is limited to a safe value thereby allowing the loads to continue functioning. The LT4356 also monitors the voltage drop between the  $V_{CC}$  and SNS pins to protect against overcurrent faults. An internal amplifier limits the current sense voltage to 50mV. In either fault condition, a timer is started inversely proportional to MOSFET stress. If the timer expires, the  $\overline{FLT}$  pin pulls low to warn of an impending power down. If the condition persists, the MOSFET is turned off. After a cool down period, the GATE pin pulls up turning on the MOSFET again.

The auxiliary amplifier may be used as a voltage detection comparator or as a linear regulator controller driving an external PNP pass transistor.

Back-to-back FETs can be used in lieu of a Schottky diode for reverse input protection, reducing voltage drop and power loss. A shutdown pin reduces the quiescent current to less than 7 $\mu$ A for the LT4356-1 during shutdown. The LT4356-2 differs from the LT4356-1 during shutdown by reducing the quiescent current to 60 $\mu$ A and keeping alive the auxiliary amplifier for uses such as an undervoltage lockout or always-on regulator.

## TYPICAL APPLICATION

4A, 12V Overvoltage Output Regulator

Overvoltage Protector Regulates Output at 27V During Transient

# LT4356-1/LT4356-2

## ABSOLUTE MAXIMUM RATINGS (Notes 1 and 2)

$V_{CC}$ , $\overline{SHDN}$	–60V to 100V
SNS	$V_{CC} - 30V$ or $-60V$ to $V_{CC} + 0.3V$
OUT, $A_{OUT}$ , $\overline{FLT}$ , EN	–0.3V to 80V
GATE (Note 3)	–0.3V to $V_{OUT} + 10V$
FB, TMR, $IN^+$	–0.3V to 6V
$A_{OUT}$ , EN, $\overline{FLT}$ , $IN^+$	–3mA
Operating Temperature Range	
LT4356C	0°C to 70°C
LT4356I	–40°C to 85°C
LT4356H	–40°C to 125°C

Storage Temperature Range	
DE12	–65°C to 125°C
MS, SO	–65°C to 150°C
Lead Temperature (Soldering, 10 sec)	
MS, SO	300°C

## PIN FUNCTIONS

**A<sub>OUT</sub> (DFN and SO Packages Only):** Amplifier Output. Open collector output of the auxiliary amplifier. It is capable of sinking up to 2mA from 80V. The negative input of the amplifier is internally connected to a 1.25V reference.

**EN:** Open-Collector Enable Output. The EN pin goes high impedance when the voltage at the OUT pin is above ( $V_{CC} - 0.7V$ ), indicating the external MOSFET is fully on. The state of the pin is latched until the OUT pin voltage resets at below 0.5V and goes back up above 2V. The internal NPN is capable of sinking up to 3mA of current from 80V to drive an LED or opto-coupler.

**Exposed Pad (DFN Package Only):** Exposed pad may be left open or connected to device ground (GND).

**FB:** Voltage Regulator Feedback Input. Connect this pin to the center tap of the output resistive divider connected between the OUT pin and ground. During an overvoltage condition, the GATE pin is servoed to maintain a 1.25V threshold at the FB pin. This pin is clamped internally to 7V. Tie to GND to disable the OV clamp.

**FLT:** Open-Collector Fault Output. This pin pulls low after the voltage at the TMR pin has reached the fault threshold of 1.25V. It indicates the pass transistor is about to turn off because either the supply voltage has stayed at an elevated level for an extended period of time (voltage fault) or the device is in an overcurrent condition (current fault). The internal NPN is capable of sinking up to 3mA of current from 80V to drive an LED or opto-coupler.

**GATE:** N-Channel MOSFET Gate Drive Output. The GATE pin is pulled up by an internal charge pump current source and clamped to 14V above the OUT pin. Both voltage and current amplifiers control the GATE pin to regulate the output voltage and limit the current through the MOSFET.

**GND:** Device Ground.

**IN<sup>+</sup> (DFN and SO Packages Only):** Positive Input of the Auxiliary Amplifier. This amplifier can be used as a level detection comparator with external hysteresis or linear regulator controlling an external PNP transistor. This pin is clamped internally to 7V. Connect to ground if unused.

**OUT:** Output Voltage Sense Input. This pin senses the voltage at the source of the N-channel MOSFET and sets the fault timer current. When the OUT pin voltage reaches 0.7V away from  $V_{CC}$ , the EN pin goes high impedance.

**SHDN:** Shutdown Control Input. The LT4356 can be shut down to a low current mode by pulling the  $\overline{SHDN}$  pin below 0.4V. Pull this pin above 2.1V or disconnect it and allow the internal current source to turn the part back on. The leakage current to ground at the pin should be limited to no more than 1 $\mu$ A if no pull up device is used to turn the part on. The  $\overline{SHDN}$  pin can be pulled up to 100V or below GND by 60V without damage. In shutdown, the auxiliary amplifier turns off in the LT4356-1 but continues operating in the LT4356-2.

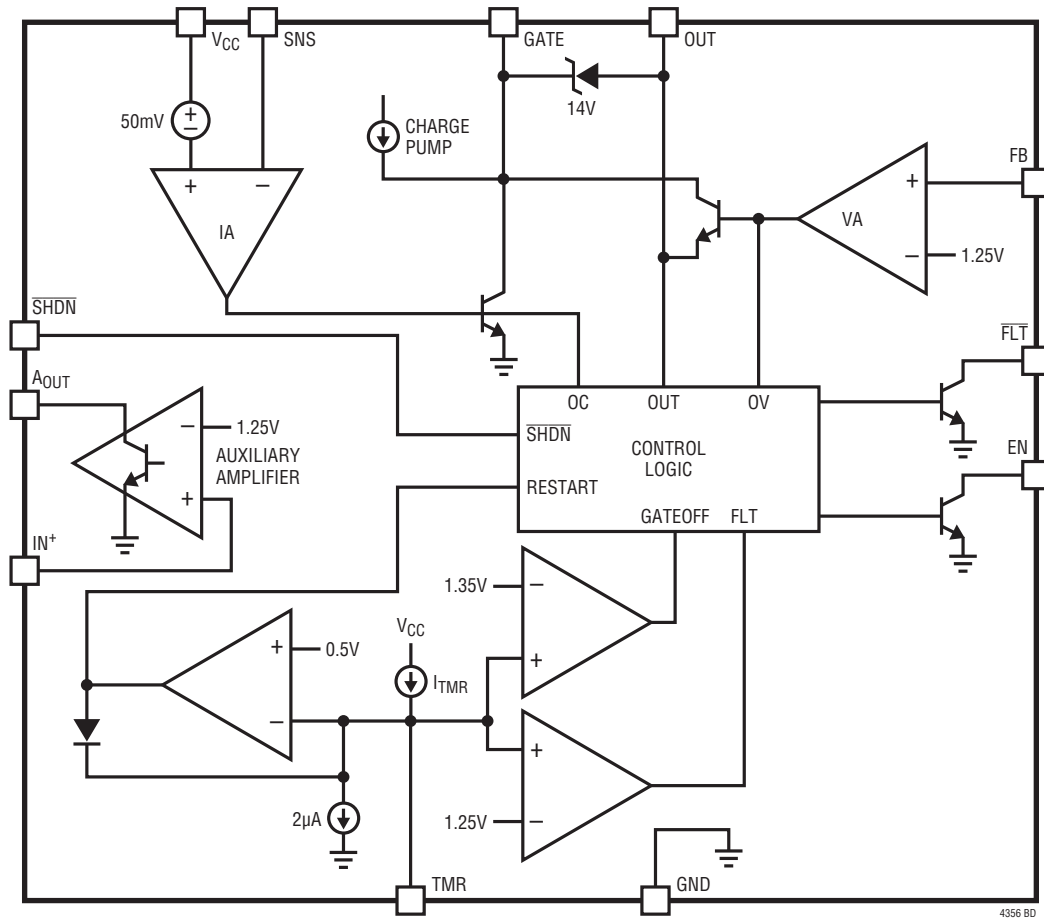

**SNS:** Current Sense Input. Connect this pin to the output of the current sense resistor. The current limit circuit controls the GATE pin to limit the sense voltage between  $V_{CC}$  and SNS pins to 50mV. At the same time the sense amplifier also starts a current source to charge up the TMR pin. This pin can be pulled below GND by up to 60V, though the voltage difference with the  $V_{CC}$  pin must be limited to less than 30V. Connect to  $V_{CC}$  if unused.

**TMR:** Fault Timer Input. Connect a capacitor between this pin and ground to set the times for early warning, fault and cool down periods. The current charging up this pin during fault conditions depends on the voltage difference between the  $V_{CC}$  and OUT pins. When  $V_{TMR}$  reaches 1.25V, the FLT pin pulls low to indicate the detection of a fault condition. If the condition persists, the pass transistor turns off when  $V_{TMR}$  reaches the threshold of 1.35V. As soon as the fault condition disappears, the pull up current stops and a 2 $\mu$ A current starts to pull the TMR pin down. When  $V_{TMR}$  reaches the retry threshold of 0.5V, the GATE pin pulls high turning back on the pass transistor.

**V<sub>CC</sub>:** Positive Supply Voltage Input. The positive supply input ranges from 4V to 80V for normal operation. It can also be pulled below ground potential by up to 60V during a reverse battery condition, without damaging the part. The supply current is reduced to 7 $\mu$ A with all the functional blocks off.

# BLOCK DIAGRAM

## OPERATION

Some power systems must cope with high voltage surges of short duration such as those in automobiles. Load circuitry must be protected from these transients, yet high availability systems must continue operating during these events.

The LT4356 is an overvoltage protection regulator that drives an external N-channel MOSFET as the pass transistor. It operates from a wide supply voltage range of 4V to 80V. It can also be pulled below ground potential by up to 60V without damage. The low power supply requirement of 4V allows it to operate even during cold cranking conditions in automotive applications. The internal charge pump turns on the N-channel MOSFET to supply current to the loads with very little power loss. Two MOSFETs can be connected back to back to replace an inline Schottky diode for reverse input protection. This improves the efficiency and increases the available supply voltage level to the load circuitry during cold crank.

Normally, the pass transistor is fully on, powering the loads with very little voltage drop. When the supply voltage surges too high, the voltage amplifier (VA) controls the gate of the MOSFET and regulates the voltage at the source pin to a level that is set by the external resistive divider from the OUT pin to ground and the internal 1.25V reference. A current source starts charging up the capacitor connected at the TMR pin to ground. If the voltage at the TMR pin,  $V_{TMR}$ , reaches 1.25V, the  $\overline{FLT}$  pin pulls low to indicate impending turn-off due to the overvoltage condition. The pass transistor stays on until the TMR pin reaches 1.35V, at which point the GATE pin pulls low turning off the MOSFET.

The potential at the TMR pin starts decreasing as soon as the overvoltage condition disappears. When the voltage at the TMR pin reaches 0.5V the GATE pin begins rising, turning on the MOSFET. The  $\overline{FLT}$  pin will then go to a high impedance state.

The fault timer allows the load to continue functioning during short transient events while protecting the MOSFET from being damaged by a long period of supply overvoltage, such as a load dump in automobiles. The timer period varies with the voltage across the MOSFET. A higher voltage corresponds to a shorter fault timer period, ensuring the MOSFET operates within its safe operating area (SOA).

The LT4356 senses an overcurrent condition by monitoring the voltage across an optional sense resistor placed between the  $V_{CC}$  and SNS pins. An active current limit circuit (IA) controls the GATE pin to limit the sense voltage to 50mV. A current is also generated to start charging up the TMR pin. This current is about 5 times the current generated during an overvoltage event. The  $\overline{FLT}$  pin pulls low when the voltage at the TMR pin reaches 1.25V and the MOSFET is turned off when it reaches 1.35V.

An auxiliary amplifier is provided with the negative input connected to an internal 1.25V reference. The output pull down device is capable of sinking up to 2mA of current allowing it to drive an LED or opto coupler. This amplifier can be configured as a linear regulator controller driving an external PNP transistor or a comparator function to monitor voltages.

A shutdown pin turns off the pass transistor and reduces the supply current to less than 7 $\mu$ A for the LT4356-1. The supply current drops down to 60 $\mu$ A while keeping the internal reference and the auxiliary amplifier active for the LT4356-2 version during shutdown.

## APPLICATIONS INFORMATION

The LT4356 can limit the voltage and current to the load circuitry during supply transients or overcurrent events. The total fault timer period should be set to ride through short overvoltage transients while not causing damage to the pass transistor. The selection of this N-channel MOSFET pass transistor is critical for this application. It must stay on and provide a low impedance path from the input supply to the load during normal operation and then dissipate power during overvoltage or overcurrent conditions.

The following sections describe the overcurrent and the overvoltage faults, and the selection of the timer capacitor value based on the required warning time. The selection of the N-channel MOSFET pass transistor is discussed next. Auxiliary amplifier, reverse input, and the shutdown functions are covered after the MOSFET selection. External component selection is discussed in detail in the Design Example section.

### Overvoltage Fault

The LTC4356 limits the voltage at the OUT pin during an overvoltage situation. An internal voltage amplifier regulates the GATE pin voltage to maintain a 1.25V threshold at the FB pin. During this period of time, the power MOSFET is still on and continues to supply current to the load. This allows uninterrupted operation during short overvoltage transient events.

When the voltage regulation loop is engaged for longer than the time-out period, set by the timer capacitor connected from the TMR pin to ground, an overvoltage fault is detected. The GATE pin is pulled down to the OUT pin by a 150mA current. After the fault condition has disappeared and a cool down period has transpired, the GATE pin starts to pull high again. This prevents the power MOSFET from being damaged during a long period of overvoltage, such as during load dump in automobiles.

### Overcurrent Fault

The LT4356 features an adjustable current limit that protects against short circuits or excessive load current. During an overcurrent event, the GATE pin is regulated to limit the current sense voltage across the  $V_{CC}$  and SNS pins to 50mV.

An overcurrent fault occurs when the current limit circuitry has been engaged for longer than the time-out delay set by the timer capacitor. The GATE pin is then immediately pulled low by a 10mA current to GND turning off the MOSFET. After the fault condition has disappeared and a cool down period has transpired, the GATE pin is allowed to pull back up and turn on the pass transistor.

### Fault Timer

The LT4356 includes an adjustable fault timer pin. Connecting a capacitor from the TMR pin to ground sets the delay timer period before the MOSFET is turned off. The same capacitor also sets the cool down period before the MOSFET is allowed to turn back on after the fault condition has disappeared.

Once a fault condition, either overvoltage or overcurrent, is detected, a current source charges up the TMR pin. The current level varies depending on the voltage drop across the drain and source terminals of the power MOSFET ( $V_{DS}$ ), which is typically from the  $V_{CC}$  pin to the OUT pin. This scheme takes better advantage of the available Safe Operating Area (SOA) of the MOSFET than would a fixed timer current. The timer function operates down to  $V_{CC} = 5V$  across the whole temperature range.

## APPLICATIONS INFORMATION

### Fault Timer Current

The timer current starts at around 2μA with 0.5V or less of  $V_{DS}$ , increasing linearly to 50μA with 75V of  $V_{DS}$  during an overvoltage fault (Figure 1). During an overcurrent fault, it starts at 4μA with 0.5V or less of  $V_{DS}$  but increases to 260μA with 80V across the MOSFET (Figure 2). This arrangement allows the pass transistor to turn off faster during an overcurrent event, since more power is dissipated during this condition. Refer to the Typical Performance Characteristics section for the timer current at different  $V_{DS}$  in both overvoltage and overcurrent events.

When the voltage at the TMR pin,  $V_{TMR}$ , reaches the 1.25V threshold, the  $\overline{FLT}$  pin pulls low to indicate the detection of a fault condition and provide warning to the load of the impending power loss. In the case of an overvoltage fault, the timer current then switches to a fixed 5μA. The interval between  $\overline{FLT}$  asserting low and the MOSFET turning off is given by:

$$t_{\text{WARNING}} = \frac{C_{\text{TMR}} \cdot 100\text{mV}}{5\mu\text{A}}$$

Figure 1. Overvoltage Fault Timer Current

Figure 2. Overcurrent Fault Timer Current

## APPLICATIONS INFORMATION

This fixed early warning period allows the systems to perform necessary backup or house-keeping functions before the power supply is cut off. After  $V_{TMR}$  crosses the 1.35V threshold, the pass transistor turns off immediately. Note that during an overcurrent event, the timer current is not reduced to 5 $\mu$ A after  $V_{TMR}$  has reached 1.25V threshold, since it would lengthen the overall fault timer period and cause more stress on the power MOSFET.

As soon as the fault condition has disappeared, a 2 $\mu$ A current starts to discharge the timer capacitor to ground. When  $V_{TMR}$  reaches the 0.5V threshold, the internal charge pump starts to pull the GATE pin high, turning on the MOSFET. The TMR pin is then actively regulated to 0.5V until the next fault condition appears. The total cool down timer period is given by:

$$t_{COOL} = \frac{C_{TMR} \cdot 0.85V}{2\mu A}$$

### MOSFET Selection

The LT4356 drives an N-channel MOSFET to conduct the load current. The important features of the MOSFET are on-resistance  $R_{DS(ON)}$ , the maximum drain-source voltage  $V_{(BR)DSS}$ , the threshold voltage, and the SOA.

The maximum allowable drain-source voltage must be higher than the supply voltage. If the output is shorted to ground or during an overvoltage event, the full supply voltage will appear across the MOSFET.

The gate drive for the MOSFET is guaranteed to be more than 10V and less than 16V for those applications with  $V_{CC}$  higher than 8V. This allows the use of standard threshold

voltage N-channel MOSFETs. For systems with  $V_{CC}$  less than 8V, a logic level MOSFET is required since the gate drive can be as low as 4.5V.

The SOA of the MOSFET must encompass all fault conditions. In normal operation the pass transistor is fully on, dissipating very little power. But during either overvoltage or overcurrent faults, the GATE pin is servoed to regulate either the output voltage or the current through the MOSFET. Large current and high voltage drop across the MOSFET can coexist in these cases. The SOA curves of the MOSFET must be considered carefully along with the selection of the fault timer capacitor.

### Transient Stress in the MOSFET

During an overvoltage event, the LT4356 drives a series pass MOSFET to regulate the output voltage at an acceptable level. The load circuitry may continue operating throughout this interval, but only at the expense of dissipation in the MOSFET pass device. MOSFET dissipation or stress is a function of the input voltage waveform, regulation voltage and load current. The MOSFET must be sized to survive this stress.

Most transient event specifications use the model shown in Figure 3. The idealized waveform comprises a linear ramp of rise time  $t_r$ , reaching a peak voltage of  $V_{PK}$  and exponentially decaying back to  $V_{IN}$  with a time constant of  $\tau$ . A common automotive transient specification has constants of  $t_r = 10\mu s$ ,  $V_{PK} = 80V$  and  $\tau = 1ms$ . A surge condition known as "load dump" has constants of  $t_r = 5ms$ ,  $V_{PK} = 60V$  and  $\tau = 200ms$ .

Figure 3. Prototypical Transient Waveform

## APPLICATIONS INFORMATION

MOSFET stress is the result of power dissipated within the device. For long duration surges of 100ms or more, stress is increasingly dominated by heat transfer; this is a matter of device packaging and mounting, and heatsink thermal mass. This is analyzed by simulation, using the MOSFET thermal model.

For short duration transients of less than 100ms, MOSFET survival is increasingly a matter of safe operating area (SOA), an intrinsic property of the MOSFET. SOA quantifies the time required at any given condition of  $V_{DS}$  and  $I_D$  to raise the junction temperature of the MOSFET to its rated maximum. MOSFET SOA is expressed in units of watt-squared-seconds ( $P^2t$ ). This figure is essentially constant for intervals of less than 100ms for any given device type, and rises to infinity under DC operating conditions. Destruction mechanisms other than bulk die temperature distort the lines of an accurately drawn SOA graph so that  $P^2t$  is not the same for all combinations of  $I_D$  and  $V_{DS}$ . In particular  $P^2t$  tends to degrade as  $V_{DS}$  approaches the maximum rating, rendering some devices useless for absorbing energy above a certain voltage.

### Calculating Transient Stress

To select a MOSFET suitable for any given application, the SOA stress must be calculated for each input transient which shall not interrupt operation. It is then a simple matter to choose a device which has adequate SOA to survive the maximum calculated stress.  $P^2t$  for a prototypical transient waveform is calculated as follows (Figure 4).

Let

$$\begin{aligned} a &= V_{REG} - V_{IN} \\ b &= V_{PK} - V_{IN} \\ (V_{IN} &= \text{Nominal Input Voltage}) \end{aligned}$$

Then

$$P^2t = I_{LOAD}^2 \left[ \frac{1}{3} t_r \frac{(b-a)^3}{b} + \frac{1}{2} \tau \left( 2a^2 \ln \frac{b}{a} + 3a^2 + b^2 - 4ab \right) \right]$$

**Figure 4. Safe Operating Area Required to Survive Prototypical Transient Waveform**

Typically  $V_{REG} \approx V_{IN}$  and  $\tau \gg t_r$  simplifying the above to

$$P^2t = \frac{1}{2} I_{LOAD}^2 (V_{PK} - V_{REG})^2 \tau \quad (W^2s)$$

For the transient conditions of  $V_{PK} = 80V$ ,  $V_{IN} = 12V$ ,  $V_{REG} = 16V$ ,  $t_r = 10\mu s$  and  $\tau = 1ms$ , and a load current of 3A,  $P^2t$  is  $18.4W^2s$ —easily handled by a MOSFET in a D-pak package. The  $P^2t$  of other transient waveshapes is evaluated by integrating the square of MOSFET power versus time.

### Calculating Short-Circuit Stress

SOA stress must also be calculated for short-circuit conditions. Short-circuit  $P^2t$  is given by:

$$P^2t = (V_{IN} \cdot \Delta V_{SNS} / R_{SNS})^2 \cdot t_{TMR} \quad (W^2s)$$

where,  $\Delta V_{SNS}$  is the SENSE pin threshold, and  $t_{TMR}$  is the overcurrent timer interval.

For  $V_{IN} = 14.7V$ ,  $V_{SNS} = 50mV$ ,  $R_{SNS} = 12m\Omega$  and  $C_{TMR} = 100nF$ ,  $P^2t$  is  $6.6W^2s$ —less than the transient SOA calculated in the previous example. Nevertheless, to account for circuit tolerances this figure should be doubled to  $13.2W^2s$ .

### Limiting Inrush Current and GATE Pin Compensation

The LT4356 limits the inrush current to any load capacitance by controlling the GATE pin voltage slew rate. An external capacitor can be connected from GATE to ground to slow down the inrush current further at the expense of slower turn-off time. The gate capacitor is set at:

$$C1 = \frac{I_{GATE(UP)}}{I_{INRUSH}} \cdot C_L$$

## APPLICATIONS INFORMATION

### Layout Considerations

To achieve accurate current sensing, Kelvin connection to the current sense resistor ( $R_{SNS}$  in Figure 9) is recommended. The minimum trace width for 1oz copper foil is 0.02" per amp to ensure the trace stays at a reasonable temperature. 0.03" per amp or wider is recommended. Note that 1oz copper exhibits a sheet resistance of about  $530\mu\Omega/\text{square}$ . Small resistances can cause large errors in high current applications. Noise immunity will be improved significantly by locating resistive dividers close to the pins with short  $V_{CC}$  and GND traces.

### Design Example

As a design example, take an application with the following specifications:  $V_{CC} = 8V$  to  $14V$  DC with transient up to  $80V$ ,  $V_{OUT} \leq 16V$ , current limit ( $I_{LIM}$ ) at  $5A$ , low battery detection at  $6V$ , and  $1ms$  of overvoltage early warning (Figure 9).

First, calculate the resistive divider value to limit  $V_{OUT}$  to  $16V$  during an overvoltage event:

$$V_{REG} = \frac{1.25V \cdot (R1 + R2)}{R2} = 16V$$

Set the current through  $R1$  and  $R2$  during the overvoltage condition to  $250\mu A$ .

$$R2 = \frac{1.25V}{250\mu A} = 5k$$

Choose  $4.99k$  for  $R2$ .

$$R1 = \frac{(16V - 1.25V) \cdot R2}{1.25V} = 58.88k$$

The closest standard value for  $R1$  is  $59k$ .

Next calculate the sense resistor,  $R_{SNS}$ , value:

$$R_{SNS} = \frac{50mV}{I_{LIM}} = \frac{50mV}{5A} = 10m\Omega$$

$C_{TMR}$  is then chosen for  $1ms$  of early warning time:

$$C_{TMR} = \frac{1ms \cdot 5\mu A}{100mV} = 50nF$$

The closest standard value for  $C_{TMR}$  is  $47nF$ .

Finally, calculate  $R4$  and  $R5$  for the  $6V$  low battery threshold detection:

$$6V = \frac{1.25V \cdot (R4 + R5)}{R5}$$

Choose  $100k$  for  $R5$ .

$$R4 = \frac{(6V - 1.25V) \cdot R5}{1.25V} = 380k$$

Select  $383k$  for  $R4$ .

The pass transistor,  $Q1$ , should be chosen to withstand the output short condition with  $V_{CC} = 14V$ .

The total overcurrent fault time is:

$$t_{oc} = \frac{47nF \cdot 0.85V}{45.5\mu A} = 0.878ms$$

The power dissipation on  $Q1$  equals to:

$$P = \frac{14V \cdot 50mV}{10m\Omega} = 70W$$

These conditions are well within the Safe Operating Area of IRLR2908.

## TYPICAL APPLICATIONS

Wide Input Range 5V to 28V Hot Swap  
with Undervoltage Lockout

24V Overvoltage Regulator Withstands 150V at  $V_{IN}$

## Overvoltage Regulator with Reverse Input Protection Up to -80V

# PACKAGE DESCRIPTION

**MS Package**  
**10-Lead Plastic MSOP**  
(Reference LTC DWG # 05-08-1661)

## NOTE:

1. DIMENSIONS IN MILLIMETER/(INCH)
2. DRAWING NOT TO SCALE
3. DIMENSION DOES NOT INCLUDE MOLD FLASH, PROTRUSIONS OR GATE BURRS.  
MOLD FLASH, PROTRUSIONS OR GATE BURRS SHALL NOT EXCEED 0.152mm (.006") PER SIDE
4. DIMENSION DOES NOT INCLUDE INTERLEAD FLASH OR PROTRUSIONS.  
INTERLEAD FLASH OR PROTRUSIONS SHALL NOT EXCEED 0.152mm (.006") PER SIDE
5. LEAD COPLANARITY (BOTTOM OF LEADS AFTER FORMING) SHALL BE 0.102mm (.004") MAX

## PACKAGE DESCRIPTION

### S Package 16-Lead Plastic Small Outline (Narrow .150 Inch) (Reference LTC DWG # 05-08-1610)

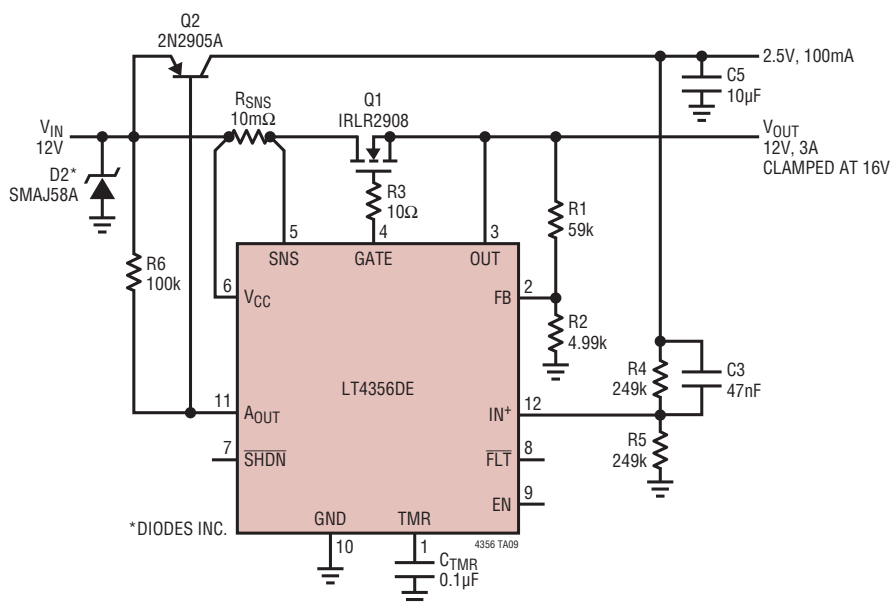

**REVISION HISTORY** (Revision history begins at Rev A)

REV	DATE	DESCRIPTION	PAGE NUMBER
A	05/10	Revised Features and Description	1
		Added parameters to $V_{OL}$ and updated Max value for $V_{SHDN(FLT)}$ in the Electrical Characteristics section	4, 5
		Revised Pin Functions section	8
		Replaced Figure 6 and made text edits in the Operation and Applications Information sections	10-17
		Updated drawings in the Typical Applications section	19, 21

## О компании

ООО "ТрейдЭлектроникс" - это оперативные поставки широкого спектра электронных компонентов отечественного и импортного производства напрямую от производителей и с крупнейших мировых складов. Реализуемая нашей компанией продукция насчитывает более полумиллиона наименований.

Благодаря этому наша компания предлагает к поставке практически не ограниченный ассортимент компонентов как оптовыми, мелкооптовыми партиями, так и в розницу.

Наличие собственной эффективной системы логистики обеспечивает надежную поставку продукции по конкурентным ценам в точно указанные сроки.

Срок поставки со стоков в **Европе и Америке – от 3 до 14 дней.**

Срок поставки из **Азии – от 10 дней.**

Благодаря развитой сети поставщиков, помогаем в поиске и приобретении экзотичных или снятых с производства компонентов.

Предоставляем спец цены на элементы для создания инженерных сэмплов.

**Упорный труд, качественный результат дают нам право быть уверенными в себе и надежными для наших клиентов.**

### Наша компания это:

- Гарантия качества поставляемой продукции
- Широкий ассортимент
- Минимальные сроки поставок
- Техническая поддержка
- Подбор комплектации
- Индивидуальный подход
- Гибкое ценообразование

Наша организация особенно сильна в поставках модулей, микросхем, пассивных компонентов, ксайленсах (XC), EPF, EPM и силовой электроники.

Большой выбор предлагаемой продукции, различные виды оплаты и доставки, позволят Вам сэкономить время и получить максимум выгоды от сотрудничества с нами!

## Перечень производителей, продукцию которых мы поставляем на российский рынок

Trade Electronics.ru

гарантия бесперебойности производства и  
качества выпускаемой продукции

С удовольствием будем прорабатывать для Вас поставки всех необходимых компонентов по текущим запросам для скорейшего выявления групп элементов, по которым сотрудничество именно с нашей компанией будет для Вас максимально выгодным!

С уважением,

Менеджер отдела продаж ООО

«Трейд Электроникс»

Шишлаков Евгений
