Spread Spectrum Generator

The device generates a clock that is frequency modulated in order to increase the bandwidth that it occupies. By increasing the bandwidth of the fundamental and its harmonics, the amplitudes of the radiated electromagnetic emissions are reduced. This effect is depicted in *Figure 1*.

As depicted in *Figure 1*, a harmonic of a modulated clock has a much lower amplitude than that of an unmodulated signal. The reduction in amplitude is dependent on the harmonic number and the frequency deviation or spread. The equation for the reduction is

$$dB = 6.5 + 9*\log_{10}(P) + 9*\log_{10}(F)$$

Where *P* is the percentage of deviation and *F* is the frequency in MHz where the reduction is measured.

The output clock is modulated with a waveform depicted in *Figure 2*. This waveform, as discussed in "Spread Spectrum Clock Generation for the Reduction of Radiated Emissions" by Bush, Fessler, and Hardin produces the maximum reduction in the amplitude of radiated electromagnetic emissions. The deviation selected for this chip is ±0.5% of the center frequency. *Figure 2* details the Cypress spreading pattern. Cypress does offer options with more spread and greater EMI reduction. Contact your local Sales representative for details on these devices.

Spread Spectrum clocking is activated or deactivated by selecting the appropriate values for bits 1–0 in data byte 0 of the I^2C data stream. Refer to *Table 4* for more details.

Serial Data Interface

The W48S87-72 features a two-pin, serial data interface that can be used to configure internal register settings that control particular device functions. Upon power-up, the W48S87-72 initializes with default register settings, therefore the use of this serial data interface is optional. The serial interface is write-only (to the clock chip) and is the dedicated function of device pins SDATA and SCLOCK. In motherboard applications, SDATA and SCLOCK are typically driven by two logic outputs of the chipset. Clock device register changes are normally made upon system initialization, if any are required. The interface can also be used during system operation for power management functions. *Table 2* summarizes the control functions of the serial data interface.

Operation

Data is written to the W48S87-72 in ten bytes of eight bits each. Bytes are written in the order shown in *Table 3*.

Table 2. Serial Data Interface Control Functions Summary

Control Function	Description	Common Application
Clock Output Disable	Any individual clock output(s) can be disabled. Disabled outputs are actively held LOW.	Unused outputs are disabled to reduce EMI and system power. Examples are clock outputs to unused SDRAM DIMM socket or PCI slot.
48-/24-MHz Clock Output Frequency Selection	48-/24-MHz clock outputs can be set to 48 MHz or 24 MHz.	Provides flexibility in Super I/O and USB device selection.
CPU Clock Frequency Selection	Provides CPU/PCI frequency selections beyond the 60- and 66.6-MHz selections that are provided by the SEL60/66 input pin. Frequency is changed in a smooth and controlled fashion.	For alternate CPU devices, and power management options. Smooth frequency transition allows CPU frequency change under normal system operation.
Output Three-state	Puts all clock outputs into a high-impedance state.	Production PCB testing.
Test Mode	All clock outputs toggle in relation with X1 input, internal PLL is bypassed. Refer to *Table 4*.	Production PCB testing.
(Reserved)	Reserved function for future device revision or production device testing.	No user application. Register bit must be written as 0.

Table 3. Byte Writing Sequence

Byte Sequence	Byte Name	Bit Sequence	Byte Description
1	Slave Address	11010010	Commands the W48S87-72 to accept the bits in Data Bytes 0–7 for internal register configuration. Since other devices may exist on the same common serial data bus, it is necessary to have a specific slave address for each potential receiver. The slave receiver address for the W48S87-72 is 11010010. Register setting will not be made if the Slave Address is not correct (or is for an alternate slave receiver).
2	Command Code	Don't Care	Unused by the W48S87-72, therefore bit values are ignored (don't care). This byte must be included in the data write sequence to maintain proper byte allocation. The Command Code Byte is part of the standard serial communication protocol and may be used when writing to another addressed slave receiver on the serial data bus.
3	Byte Count	Don't Care	Unused by the W48S87-72, therefore bit values are ignored (don't care). This byte must be included in the data write sequence to maintain proper byte allocation. The Byte Count Byte is part of the standard serial communication protocol and may be used when writing to another addressed slave receiver on the serial data bus.
4	Data Byte 0	Refer to *Table 4*	The data bits in Data Bytes 0–7 set internal W48S87-72 registers that control device operation. The data bits are only accepted when the Address Byte bit sequence is 11010010, as noted above. For description of bit control functions, refer to *Table 4*, Data Byte Serial Configuration Map.

Writing Data Bytes

Each bit in the data bytes control a particular device function except for the “reserved” bits which must be written as a logic 0. Bits are written MSB (most significant bit) first, which is bit 7. *Table 4* gives the bit formats for registers located in Data Bytes 0–7.

Table 5 details additional frequency selections that are available through the serial data interface.

Table 6 details the select functions for Byte 0, bits 1 and 0.

How To Use the Serial Data Interface

Electrical Requirements

Figure 3 illustrates electrical characteristics for the serial interface bus used with the W48S87-72. Devices send data over the bus with an open drain logic output that can (a) pull the bus line LOW, or (b) let the bus default to logic 1. The pull-up resistors on the bus (both clock and data lines) establish a default logic 1. All bus devices generally have logic inputs to receive data.

Although the W48S87-72 is a receive-only device (no data write-back capability), it does transmit an “acknowledge” data pulse after each byte is received. Thus, the SDATA line can both transmit and receive data.

The pull-up resistor should be sized to meet the rise and fall times specified in AC parameters, taking into consideration total bus line capacitance.

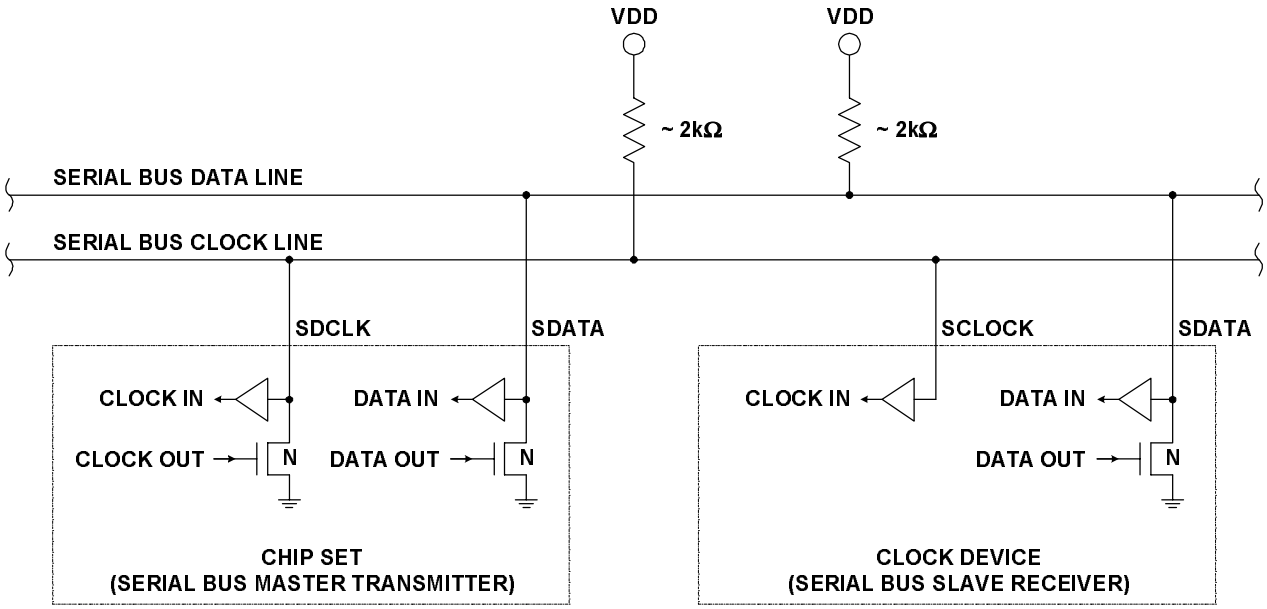

Figure 3. Serial Interface Bus Electrical Characteristics

Signaling Requirements

As shown in *Figure 4*, valid data bits are defined as stable logic 0 or 1 condition on the data line during a clock HIGH (logic 1) pulse. A transitioning data line during a clock HIGH pulse may be interpreted as a start or stop pulse (it will be interpreted as a start or stop pulse if the start/stop timing parameters are met).

A write sequence is initiated by a “start bit” as shown in *Figure 5*. A “stop bit” signifies that a transmission has ended.

As stated previously, the W48S87-72 sends an “acknowledge” pulse after receiving eight data bits in each byte as shown in *Figure 6*.

Sending Data to the W48S87-72

The device accepts data once it has detected a valid start bit and address byte sequence. Device functionality is changed upon the receipt of each data bit (registers are not double buffered). Partial transmission is allowed meaning that a transmission can be truncated as soon as the desired data bits are transmitted (remaining registers will be unmodified). Transmission is truncated with either a stop bit or new start bit (restart condition).
